Repeated rumors have come from more or less official sources regarding startling developments in these fields. The latest report (the *Nation's Business*, April, 1920, p. 76) calls attention to the development of lignite as a possible solution of Great Britain's oil problem, and specially to the production of Montan wax from this lignite which, up to the present, has been a complete monopoly of Austria and Germany.

Nature and Uses of Montan Wax

Montan wax comes into commerce as a white, high-melting candle-like material. It is not a paraffine, but a mixture of an acid and an alcohol. While it decomposes when distilled at ordinary pressure, it may be purified by distillation with superheated steam in vacuum.

Montan wax is valuable as a substitute for carnauba wax in the manufacture of shoe polishes, and is also used in the manufacture of phonographic records, and as an insulating material in place of ceresin (purified ozokerite).

Montan Wax From Pyropissite

The best source of Montan wax is the mineral pyropissite, which may contain as high as 70 per cent. This supply, however, is largely exhausted. The next best material is lignite from Thuringen, Saxony, with about 9 per cent Montan wax, although in exceptional cases as high as 20 per cent has been obtained. All the other lignites examined run somewhat below 5 per cent Montan wax.

Montan Wax From Lignite

Some years ago Arthur D. Little, Inc., made an exhaustive examination of the lignite deposits of Canada, with special reference to the possibility of obtaining Montan wax. Samples were obtained from Bienfait, Sask.; Taber, Lethbridge, Drumbellen, and Morimville, Alta.; Nicola, B. C., and Princeton, B. C. Samples of brown lignite from the Estavan district of southern Saskatchewan were also examined. In only one case was Montan wax (benzol extract) found, and that was so small as to be commercially unimportant. When this work had been completed, it was learned that the Standard Oil Co. had made a similar search with similar results.

Montan Wax From Peat

Ryan and Dillon (*Proc. Roy. Dublin Soc.*, 1909) have obtained waxes of very similar properties from certain deposits of Irish peat. Peat is one of the stages lower than lignite in coal formation and so a large number of samples of peats from various Canadian bogs were examined in the same way. All of them were found to contain a small percentage of wax, very similar in characteristics to Montan wax, though not identical with it. In all cases, however, the amount was from 5 per cent downward (on the dry basis) and would not justify the commercial utilization of peat for this purpose.

Arthur D. Little, Inc.

Report of the Rubber Division Meeting and Cellulose Symposium of the A. C. S. at St. Louis

Notes on Physical Testing—Bromine Addition—Value of Shoddy—Recovery of Solvents—Determination of Sulphurs—Accelerators—Dispersion of Pigments—Effect of Compounding Ingredients—Microscopic Testing—Colloidal Studies—Testing of Pigments—Papers on Cellulose

THE second meeting of the Rubber Division of the American Chemical Society, which was held at St. Louis, April 14 and 15, 1920, was even more of a success than that of last September in Philadelphia. The rubber chemists of the country are becoming acquainted. They have met, admired, and are beginning to understand and appreciate the other fellow. Information may be divided into two classes, the purely scientific and that which has trade value, such as trade secrets, formulas, etc. It is recognized that the latter should not be made common property, but it has always proved true that free and open discussion of the fundamentals not only puts the industry on a firm basis but gives one fresh inspiration, new ideas and new applications. The benefits of co-operation in things scientific are apparent. The whole tone of this meeting reflected the willingness of the members to discuss the scientific fundamentals of the industry with material benefit to all concerned.

The papers were not so numerous as at Philadelphia and the discussion of each was in every case of considerable value. It is to be hoped that before the next meeting the members of the division will be provided with abstracts of the papers to be given ahead of time so that they can collect their own data and enter into the discussions to the fullest extent.

Report of the Committee on Physical Testing

Tentative specifications were presented last September, at which time the matter was referred back to the committee so that comments, criticisms, etc., might be submitted. J. M. Bierer called the committee's attention to an apparent error in the bursting test for hose, which was later found to be a typographical error consisting of the omission of the decimal point. W. W. Evans suggested that for the time being both English and metric systems should be used, but that later we should gradually work over to the metric system. The permanent set test as outlined was criticized as long and cumbersome. On the other hand, if a real measure of plasticity is desired some such test is very necessary. Mr. North said that the test could be shortened to three stretches to 60 per cent of the breaking elongation, each held 3 min., with a 1-min. interval between, measuring 10 min. after the third release. Discussion was closed by passing a motion referring the whole proposition back to the committee, which was instructed to co-operate with all parties interested in rubber testing, e.g., Bureau of Standards, Rubber Association, etc., for the development of methods which will be standard throughout the United States.

Bromine Addition to Rubber

W. K. Lewis and William H. McAdams showed that the addition of bromine to rubber may be quickly measured volumetrically and that the disappearance of bromine when corrected for combined sulphur is a direct measure of the rubber hydrocarbon in the stock. The method is not applicable to determining the coefficient of vulcanization. Certain substances, of which MR is the principal offender, were shown to interfere. Dr. Lewis gave some results which checked the actual rubber content of the stocks very closely.

Relative Value of Shoddy in Mechanical Rubber Goods

The question as to when reclaimed rubber ceases to be economical has always been a serious one for makers of the various mechanicals, such as hose, packing, heels, etc. J. M. Bierer gave his findings, but little as to the methods by which his conclusions were arrived at. He presented a very interesting chart showing variation of relative values of reclaim, scrap, and crude rubber, from which it is possible, knowing the market price of crude rubber, to find the price at which tire carcass and shoe shoddy reclaims become unprofitable. From another section of the chart maximum allowable prices for these scraps, depending as before on the price of crude rubber, may be found.

Recovery of Volatile Solvents

Dr. W. K. Lewis discussed the two methods of solvent recovery, which are by absorption, and by compression and cooling. The first one requires that the spreaders be inclosed and that the solvent vapors be swept away by inert gas, thus preventing explosions. The solvent is washed out of the gas in a manner not greatly different from coal gas scrubbing. A 90 per cent recovery on large-scale operation is possible, but considerable funds are required in the initial outlay.

Where the vapors are more highly saturated the compression and cooling method is satisfactory. Not such a large initial expenditure is required.

Determination of True Free and True Combined Sulphur in Vulcanized Rubber

Dr. W. J. Kelly pointed out that the method of determining combined sulphur by subtracting acetone soluble sulphur from total sulphur is erroneous. The acetone soluble sulphur consists of true free sulphur and sulphur combined with certain resins. These may be separated by treating the acetone extract with alcohol previously saturated with sulphur. In this way the resins with their combined sulphur dissolve but leave behind the true free sulphur.

When the extracted sample is boiled with alcoholic potash, practically all of the acetone insoluble resins with their combined sulphur are saponified and removed. Boiling alcoholic potash also removes any sulphur that may be combined with rubber proteins.

This is a very valuable contribution, and should give new impetus to the study of the relation between coefficient of vulcanization and physical properties.

C. R. Boggs pointed out that free sulphur may be measured by suspending a roll of copper gauze in the acetone during extraction. Increase in weight gives free sulphur directly.

Small Amounts of Magnesia and Certain Organic Substances as Accelerators

A paper on this subject was presented by G. D. Kratz and A. H. Flower. The authors compared small amounts of magnesia with various organic accelerators. They advanced the opinion that magnesia functions as a secondary accelerator, i.e., it aids other substances, probably always nitrogenous, in producing the true accelerator which is yet to be discovered.

Dispersing Power of Pigments

W. K. Lewis and F. P. Baker stated that the dispersing power of pigments is a very interesting method for comparing average fineness of a pigment with other samples of the same pigment. When for one sample the dispersing power and size of particle, measured microscopically, are known, the average size of particle of other samples may readily be determined. The method consists essentially of working up a weighed quantity of pigment in linseed oil, diluting it with suitable solvent and measuring the weight of the column of liquid required to obscure the filament of an electric light.

Possibility of comparing fineness of different pigments was discussed. J. R. McGregor pointed out that the index of refraction of the pigments and of the liquid media has a considerable influence, at least in some instances, on such results.

Effect of Compounding Ingredients on the Physical Properties of Rubber

Compounding experiments with varying volume ratios of the more common fillers were described by C. O. North. Value of the pigments mentioned is in following order: Gas black, zinc oxide, magnesium carbonate, tripoli, lithopone and barytes. Mr. North proposed a new method for aiming at the effect of the filler on the rubber regardless of how that effect is produced. Values for the ordinary tests were referred back to the actual volume of rubber present.

The practice of making comparisons on a basis of tensile strength is unfair to stocks high in rubber. Tensile at break was advanced as a better procedure. This is secured by multiplying tensile strength as ordinarily obtained by the final length, dividing by the original length and correcting for volume increase during stretching. Such curves are parallel to those for Stevens Tensile Product value.

A visualization of the physical structure of rubber was presented, i.e., the network hypothesis which is based on the assumption that large colloidal aggregates function as elastic fibers and the shorter ones as plastic material. It is not improbable that the chief effect of vulcanization is to lock up these fibers to form a network. The finer the compounding ingredient the more loops there are to this net and the stronger and tougher the stock.

The reading of this paper was followed by considerable discussion. W. B. Weigand stated that his own data checked Mr. North's very closely. He is of the opinion that the effect of compounding ingredients is largely due to their surface energy. The similarity of the views of the two investigators was quite apparent. The only difference is that the one has created a mechanical hypothesis for purposes of visualization, while the other applies the more or less intangible surface energy, adsorption theory of the colloid chemist.

Microscopic Examination of Rubber Products

H. J. Masson and Irene Diner presented a paper on the application of metallographic and biological methods of microscopy to the examination of rubber. This will no doubt prove a very productive field for research. This paper is the first on this subject.

The technique of the authors is to be commended. Unfortunately they did not have the co-operation of any rubber technologist, and as a result their conclusions were somewhat exaggerated. A very interesting series of photographs was shown.

Rubber Chemistry From the Colloidal Viewpoint

E. B. Spear presented a discussion of coagulation, polymerization, and the effect of compounding ingredients on rubber from the standpoint of one versed in colloidal chemistry. It is hoped that quantitative data may be obtained which will permit of practical application of the colloid theories to the rubber industry.

Symposium on the Testing of Pigments

B. F. Goodrich Co. methods of sampling, testing, and analysis of pigments for compounding were described by W. W. Evans. It was found that the methods of other chemists agreed well with those described by Mr. Evans.

New Business

George Oenslager resigned from the executive committee because of an extended visit to the Orient.

Standardized methods of rubber analysis are booked for discussion at the next meeting.

No action was taken toward a unified method of testing crude rubber. It was the opinion of those present that the various manufacturers preferred their own methods, which for the time are probably satisfactory.

The division took a firm stand against the attempt of some manufacturers to sell accelerators to the rubber industry solely under trade names. In the first place the chemists in attendance agreed not to test such accelerators and in the second the Rubber Division promises to declare the true composition of every accelerator so marketed. This action was taken because of the introduction of an accelerator said to consist of starch and sodium hydroxide, and also the growing tendency to incorporate such substances as barium sulphate into accelerators which are sold at high prices per pound. Trade names are not objected to if the true percentage composition of the accelerator is given at the same time. C. O. North, Frederic Dannerth, C. W. Bedford and H. A. Depew took part in the discussion preliminary to the passing of the above motion.

The marked success of this meeting is merely a beginning. It is hoped that the chemists of every rubber company will endeavor to present at least one paper per year.

In closing this review, the efforts of the chairman, Dr. Warren K. Lewis, of the Massachusetts Institute of Technology, who ran true to form in leading discussion and in generally making the meeting a "go," are to be particularly commended. The highly efficient secretary, Arnold H. Smith, of the Goodyear Tire & Rubber Co., is also to be congratulated on the way he handled his work.

Cellulose Symposium

The advocates of the establishment of a Cellulose Section more than proved its desirability both by providing an excellent program and attracting an attendance of nearly 500 members. Through a misunderstanding, the member of our staff who was to report on the papers of this symposium did not do so, but we are pleased to give the following notes as received from Dr. Gustavus J. Esselen, Jr., of A. D. Little, Inc.:

The Mechanism of the Reactions of Cellulose. J. E. Minor. Miss Minor's paper was presented in abstract. It was a continuation of the work, part of which she published in *Paper*, vol. 25, p. 700 (1919). She looks at cellulose from the modern viewpoint, which regards it as a colloid, and on this basis she considered in her paper a number of the reactions of cellulose, such as oxidation, hydration and solution. Her paper is one of the few which have attempted to present cellulose chemistry from the modern viewpoint. It is a very valuable contribution.

Some Observations on the Determination of Cellulose in Wood. S. A. Mahood. Dr. Mahood's paper presented some recent work of the Forest Products Laboratory at Madison, in which they have studied the determination of cellulose in wood samples, with special reference to the degree of subdivision of the sample analyzed.

Nitrocellulose From Wood Pulp. R. C. Woodbridge, Jr. This paper was presented by title. It appeared in the *Journal of Industrial and Engineering Chemistry* for April, 1920, on p. 380.

Notes on the Manufacture of Nitrocellulose. J. O. Small and C. A. Higgins. This paper was presented in abstract form. It contains a very thorough survey of the many important factors involved in the preparation of nitrocellulose for different purposes.

Certain Aspects of the Chemistry of Cellulose Acetate From the Colloidal Viewpoint. G. J. Esselen, Jr. In this paper, after a brief consideration of some of the colloidal principles involved in the preparation and solution of cellulose acetate, the author presented a theory which attempts to explain why alcohol improves the solubility of cellulose in chloroform and tetrachlorethane and to connect this phenomenon with the known fact that cellulose acetate is soluble in mixtures of alcohol and benzol and in phenols, but is not soluble in alcohol mixed with aliphatic hydrocarbons.

Projects of the Preliminary Committee on American Cotton Research. H. E. Howe. This was a brief outline by Mr. Howe of some of the things in which the committee is trying to interest the cotton manufacturers.

Is It Advisable to Form a Section of Cellulose Chemistry? Jasper E. Crane. Since Mr. Crane was on his way to London, this was a letter from him urging the establishment of a section of cellulose chemistry. The symposium at St. Louis was organized by Mr. Crane.

Cellulose Phthalate; Its Preparation and Properties. H. A. Levey. In this paper there was presented some work carried out by the author for the Bureau of Aircraft Production during the war. The object was to prepare a cellulose ester for use in airplane dopes which would not require acetate of lime, either for its preparation or solution. As raw material, powdered cellulose hydrate was used. Owing to the solid character of the phthalic anhydride, considerable difficulty was experienced in the esterification. A product was obtained which the author claimed corresponded to one molecule of phthalic acid combined with eight molecules of cellulose. Because of the low degree of esterification, no solvents had been found for the material. The work was interrupted by the signing of the armistice.

Production of Petroleum in Mexico

It is impossible to give the exact number of wells under exploitation at present in the Mexican fields, if by exploitation is meant the actual extraction of oil from the wells; nor is it easy to determine the daily production of petroleum, since this is dependent on the industrial needs of the companies, the orders they may have pending, and especially on the available means of transportation. On Nov. 1, 1919, the wells actually producing petroleum numbered 305, with a daily production of 317,000 cu.m., or approximately 2,000,000 bbl. Of course, it is not possible to operate the wells continually at full capacity, nor is it reasonable to expect that the productive capacity of a given well will remain constant for an indefinite period; therefore any speculation as to the productive capacity of the wells is only a relative value. However, even though only 50 per cent of the wells be exploited, and allowing for errors in estimating their possible production, it is safe to say that the Mexican wells now under exploitation are capable of producing 170,000 cu.m. of petroleum per day, or about 1,000,000 bbl.

During the year 1919 exports of petroleum from the various ports were as follows:

	Tons
Tampico	6,342,950
Tuxpam and Puerto Lobos	4,638,511
Puerto Mexico	264,482
Other ports	682
Total	11,246,626

About 75,700,000 barrels.

Official figures showing the value of these exports are not available, but 186,500,000 Mexican pesos has been stated as being an approximate value. Taxes collected for the year were 15,203,986 Mexican pesos.

Refineries Under Construction

The Mexican Government has done everything possible to favor and develop the industry of refining petroleum in the country, in the belief that this branch of the industry would lead to the greater industrial development of Mexico by furnishing the necessary derivative products, offering employment on a large scale, and utilizing to a great extent national resources. Therefore, numerous concessions for the establishment of refineries have been granted, and a great number are now under construction. During the year 1918 there were refined in Mexico 3,795,000 tons of crude petroleum, fuel oil occupying the first place among the refined products, with a total production of 2,883,000 tons. During the same year refined products made up 34 per cent of the total exports of petroleum, which amounted to 7,676,864 tons, and it is estimated that during the year 1919 there was exported 2,653,000 tons of refined petroleum products.

Research in the Non-Benzenoid Hydrocarbon Series

A Constructive Discussion Emphasizing Certain Points in Organic Chemistry—Grouping of Open Chain and Non-Condensed Ring Hydrocarbons—Limits of Applicability of Certain Type Reactions—Influence of Adjacent Radicals—Molecular Rearrangement—Field for Industrial Research

By BENJAMIN T. BROOKS

THE beautiful, interesting, and often facile chemistry of the benzene hydrocarbons has somewhat overshadowed the chemistry of the aliphatic open chain and non-condensed cyclic hydrocarbons. Certainly the chemistry of the former series has been much more fully rounded out. Judging from the customary method of treatment accorded them in our textbooks, there is some confusion in the arrangement of subject matter which does not give the student a proper idea of the close relationships and similarity of chemical behavior possessed by all the non-benzenoid hydrocarbons.

Part of this confusion has probably arisen from the frequent use of the term "hydro-aromatic" hydrocarbons. This term is still employed for cyclohexane and its simple derivatives, although its behavior is almost identical with that of normal hexane. The same applies to cyclopentane and its simple derivatives as compared with normal pentane, yet cyclopentane cannot be termed a "hydro-aromatic" hydrocarbon. Cycloheptane, cyclo-octane, cyclononane, cyclobutane, cyclopropane and ethylene should certainly be classed and described together with cyclohexane, as indeed Aschan and a few others have done. The differences in chemical properties between condensed ring systems of the benzene type and the non-condensed or *non-benzenoid* hydrocarbons are well established, but in spite of the enormous amount of work done, have not yet received adequate explanation.

It is a curious fact that during recent years a great part of the research in the field of the non-benzenoid hydrocarbons has been done in Russia, and most of this work has been very imperfectly abstracted, mostly through German publications. It is difficult indeed to estimate what may be the fate of scientific research in that unfortunate country during the next generation, and it seems worth while therefore to call attention to this relatively neglected field of research.

As regards the aliphatic hydrocarbons proper, these fare very badly in most works on organic chemistry, particularly the briefer textbooks. Usually, the entirely erroneous statement, or implication, is made that the so-called type reactions given for the first two or three members of the methane series hold good for the higher members. Beyond the fact that all of them may be completely burned to carbon dioxide and water, such statements are hardly in accord with the known facts.

Well Developed Sections of Organic Chemistry

The chemistry of the aliphatic and alicyclic series of hydrocarbons may conveniently be classified into certain special chapters, the chemistry of which has in most cases been greatly extended and generally well surveyed. Thus the fatty acids and the chemical technology of the fats and fatty oils; the sugars, starches and celluloses; the amino acids and polypeptides; and the simpler alcohols and the chemical technology of alcoholic fermentation, represent comparatively sharply defined subjects, our knowledge of which is constantly being systematically extended by specialists in these fields of work. When we turn, however, to the non-condensed or non-benzenoid hydrocarbons and their simpler derivatives, we note that the chemistry of the first five members of the methane series and also the ten-carbon-atom or terpene group, mostly cyclic hydrocarbons, have been much more extensively and carefully studied than the remainder. Some of the reasons for this are fairly apparent. Thus, the essential oils afford a convenient source of substances of the terpene group which may generally be isolated easily in a state of purity. The natural fatty glycerides or other convenient sources readily yield a limited number of fatty acids, nearly all of them normal, i.e., acids of one, two, three, four, five, six, eight, ten, twelve, fourteen, sixteen, eighteen and twenty-four carbon atoms. Research in many of these special fields has accordingly been greatly facilitated by the availability of suitable material and has often been much stimulated by an intimate relation to industry.

It may also be pointed out that while in the aromatic series a rich variety of raw materials is easily isolated or prepared, crystalline derivatives are almost the rule, permitting easy purification, identification and manipulation in small quantities; that substitutive reactions are usually capable of control to form chiefly one product or a very limited number of products or isomers; but in the aliphatic series this is not the case. Petroleums probably contain all of the normal paraffine hydrocarbons up to $C_{26}H_{54}$ and perhaps farther in the series, and also most of the more stable naphthenes which are theoretically possible but for the most part yet unknown. Not only is it at present impossible to isolate individual substances from this complex raw material, but methods of synthesis applicable to the higher members have not yet been developed.

Probably the most careful work on the separation of the hydrocarbons by fractional distillation of hydrocarbons has been done by Young and his co-workers. They have shown that in the case of a mixture containing only pentane and isopentane, boiling points 36.3 and 27.9 deg. respectively, no less than thirteen carefully conducted fractional distillations, using a very efficient column, were necessary to effect separation of these two substances in a fair degree of purity. It is extremely probable therefore that most of the older work reporting the isolation of a great number of hydrocarbons from petroleum is entirely erroneous, and that the laborious distillation of petroleum fractions—for example, the "isolation" of a fraction boiling at say 212 to 216 deg. and calling it dodecane on the basis

of an analysis agreeing approximately with the formula C_nH_{2n+2} or $C_{12}H_{26}$—is nothing more or less than a lamentable waste of time.

Limit of Applicability of Certain Type Reactions

Most textbooks of organic chemistry give a number of type reactions which have a certain preparative value in the group methane to pentane inclusive. These reactions are usually briefly stated without any qualifications, even when the reactions as written represent only 10 per cent of the total result. Alkyl iodides are often preferred in reaction writing, probably for the reason that some early writer started the custom, although as Nef has shown for the ether reaction

$$RONa + R_1X \rightarrow ROR_1 + NaX$$

iodides give much poorer yields than bromides or chlorides and that the amyl iodides give olefines practically quantitatively (and this undoubtedly holds for the higher alkyl iodides). The Williamson synthesis has not been successfully carried out with alkyl halides containing more than eight carbon atoms, and nearly all of the amyl, hexyl, heptyl and octyl ethers now supposedly known were described in a single paper and this work has apparently not been repeated. It may also be pointed out that the sulphuric-acid method commonly used in preparing ethyl ether is not applicable to alcohols above butyl in the series.

The Grignard reaction has been a most valuable method of synthesis, yet this reaction also is practically valueless for alkyl halides containing more than six carbon atoms. As pointed out by Grignard and others, the higher alkyl halides not only react very slowly with magnesium but the principal reaction which does take place is the following:

$$RMgX + RX \rightarrow R\text{–}R + MgX_2$$

Thus a bromo hexane will give $C_{12}H_{26}$ almost exclusively.

$$C_6H_{13}MgBr + C_6H_{13}Br \rightarrow C_{12}H_{26} + MgBr_2$$

The above examples are cited in protest against the all too common practice of describing reactions applicable to ethane derivatives as type reactions of the whole aliphatic series.

Instability of the Alkyl Halides

Many of the familiar reactions which fail with the derivatives of the higher paraffines do so on account of the instability of the alkyl halides. Most of the methods of preparing alcohols fail with the higher alcohols, and the most useful method is that of Bouveault and Blanc, i.e., reduction of the ethyl esters of the fatty acids by metallic sodium in absolute alcohol, which method is therefore practically limited to the natural fatty acids. (Conversion of the natural fatty acids of an even number of carbon atoms to acids of odd number of carbon atoms is effected only with some difficulty by Krafft's method or through the α-bromo acids or the amides.) According to some very early work, apparently not since confirmed or extended, the condensation of the higher alkyl halides by metallic sodium to hydrocarbons and sodium halides

$$2C_{10}H_{21}X + 2Na \rightarrow C_{20}H_{42} + 2NaX$$

proceeds with much better yields in the case of the higher alkyl halides than with the simpler members. Judging from the work of Nef on ether formation, the chlorides should give much better yields than bromides or iodides.

A property of the higher alkyl halides which does not appear to have been carefully investigated is their reaction with alkali cyanides, hydroxides, sodium malonic ester, aniline, quinoline, etc., to give in part saturated hydrocarbons. With sodium cyanide, for example, one would expect largely olefine and a little alkyl cyanide or nitrile; with caustic alkali one would expect olefine and a little ether. But ring formation occurs to a considerable extent, with the elimination of halogen acid from two carbon atoms which may be near each other in space, as

$$\begin{matrix} CH_2CH_2CHH{-}R \\ | \\ CH_2CH_2CH_2Br \end{matrix} \rightarrow \begin{matrix} CH_2CH_2CH{-}R \\ | \quad | \\ CH_2CH_2CH_2 \end{matrix} + HBr$$

analogous to the formation of the cyclo propane ring by elimination of HBr from bromodimethyl glutaric ester (Perkin and Thorpe, *J. Chem. Soc.*, vol. 75, p. 48) and the reaction

$$CH_3COCH_2CH_2CH_2Br + NaOH \rightarrow CH_3COCH\text{——}CH_2$$
$$\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad CH_2$$

observed by Lipp (*Ber.*, vol. 22, p. 1,207).

Influence of Adjacent Radicles

The properties of the ethylene bond present an array of incompletely solved problems. Here again the briefer textbooks of organic chemistry usually present a number of type reactions without qualifications, whereas it is not too much to say that the properties of the ethylene bond depend very largely upon the character of the groups or atoms adjacent or near to it.

Thiele's well-known theory of partial valence attempted to account for many observed peculiarities of conjugated double linkings. The addition of halogens, particularly bromine, to olefines is commonly stated to be a characteristic reaction, but it should be pointed out that there is probably every gradation in speed of reaction between bromine and substituted ethylenes, from ethylene and propylene which combine with bromine at —80 deg. with a velocity too great to be experimentally measured (Plotnikov), to the substituted ethylenes containing several strongly electro-negative groups, studied by Bauer (*Ber.*, vol. 37, p. 3,317; 1904), which are entirely inert to bromine. Reactions which are less energetic than the addition of bromine are often markedly affected by minor structural differences. One case in which advantage is taken of such behavior is in the manufacture of isoprene from normal pentane by one of the Badische processes. The process yields a mixture of normal and iso amylenes. On treating with HCl the latter reacts only with the amylene

$$\begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!>\!C{=}CH.CH_3 + HCl \rightarrow \begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!>\!CCl.CH_2CH_3$$

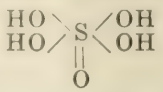
and this reaction product may then be separated by distillation and the unchanged amylenes put through the isomerizing process again.

The addition of water to olefines by means of aqueous sulphuric acid has heretofore been assumed to take place exclusively through the hydrolysis of alkyl sulphuric esters,

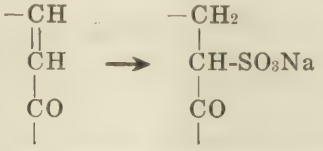
$$\begin{matrix} R\,CH \\ \| \\ R_1CH \end{matrix} \rightarrow \begin{matrix} R\,CH_2 \\ | \\ R_1CHOSO_3H \end{matrix} + H_2O \rightarrow \begin{matrix} R\,CH_2 \\ | \\ R_1CHOH \end{matrix} + H_2SO_4.$$

This reaction is best carried out in the cold and the alcohol is separated by pouring into ice water, yet the

alkyl sulphuric esters made by the action of sulphuric acid on alcohols are not appreciably hydrolyzed by water at 0 deg. Other evidence also points to the possibility that hydration of olefines by aqueous sulphuric acid is due to the intermediate formation of unstable esters of ortho sulphuric acid $H_2SO_4H_2O$ or



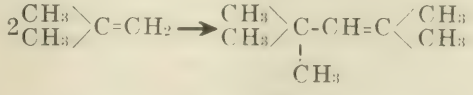
An American petroleum company has recently undertaken the manufacture of a series of the simpler secondary and tertiary alcohols from petroleum or oil gas olefines. In connection with the addition of water to olefines by aqueous sulphuric acid, it may be recalled that in a few instances water alone will react with the double bond, as with the ketenes $(R)_2C{=}CO$. Also the remarkable reactivity of the olefine bond in the group –CH=CH–C=O– has been the subject of considerable research and speculation. Substances containing this group are often easily "hydrolyzed" by dilute acids with rupture of the carbon chain, e.g., mesityl oxide, citral, pulegone, etc. The extreme reactivity is also shown by their ability to combine directly with a wide variety of substances. The addition of sodium acid sulphite to carvone, citral, citronellal and the like to give stable sodium sulphonates of the type



is well known, but the addition of malonic ester, aceto acetic ester and hydrocyanic acid to olefines of this type is perhaps not so well known. It may be of interest to note that the group –CH=CH.CO– is also necessary to the perfume value of many substances, for example ionone.

Polymerization

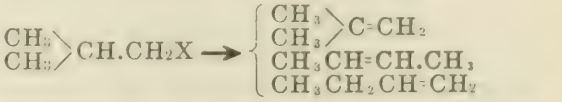
One of the most common and yet obscure properties of olefines is their tendency to polymerize. Conjugated diolefines possess this property to a high degree, as is now well known through the researches on the preparation of synthetic rubbers from butadiene, isoprene and dimethyl butadiene. Very few simple cases of polymerization have been studied, but Kondakow (*J. prakt. Chem.*, N. F. 54, p. 447; 1896) showed that di-isobutylene possesses the constitution indicated in the following:



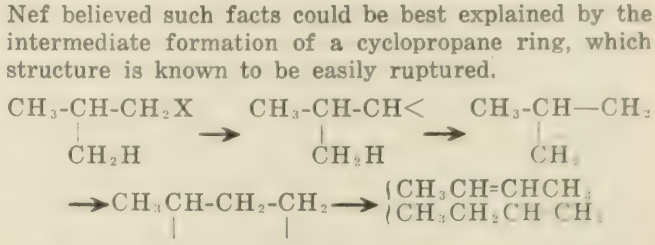
Such polymerization may be effected by a wide variety of substances. In the case of concentrated sulphuric acid, which is known to form alkyl sulphuric esters at least in part, it is not difficult to construct a theory by which such changes may be accounted for. But the mechanism of polymerization under the influence of metallic sodium, heat and light is not so easy—in fact it is entirely obscure. The mechanism of the polymerization of hydrocarbons is undoubtedly intimately connected with the fundamental properties of molecules and our theories of valence. Further information regarding the effect of heat and light on the vibration or "loosening" of the valency electrons will undoubtedly go far to explain the polymerization of olefines, as well as the shift in position of double bonds which is so frequently observed to occur.

Instability of Molecular Structure

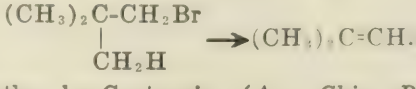
Mobility or instability of the carbon atom structure is one of the most striking properties of non-benzenoid substances. Thus isobutyl alcohol and the primary isobutyl halides yield a mixture of butylenes which has been shown to contain isobutylene and α and β normal butylenes.



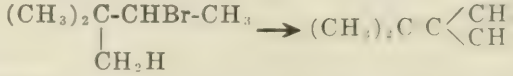
Nef believed such facts could be best explained by the intermediate formation of a cyclopropane ring, which structure is known to be easily ruptured.



A similar example has been reported by Tissier (*Ann. Chim. Phys.*, Ser. 6, vol. 29, p. 361.)

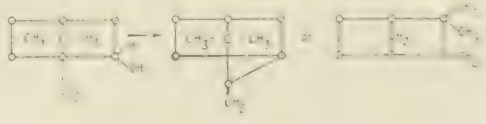


and another by Coutourier (*Ann. Chim. Phys.*, Ser. 6, vol. 26, p. 464).

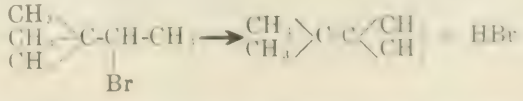


Other well-authenticated and striking changes in structure occur in the cyclic series, the change of the six carbon ring to the seven carbon ring, the change of the six carbon ring to the five carbon ring and vice versa and particularly the series of such cases recently studied by Meerwein (*Ann. Chemie*, vol. 376, p. 152, 1910; vol. 405, p. 129, 1914; vol. 417, p. 255, 1918) in his study of camphene and the borneols. Thus Meerwein has proved that 1.1 methyl α oxethyl cyclopentane on dehydration yields dimethyl cyclohexene

analogous to the structural changes in the formation of camphene from isoborneol by loss of water



Probably the best known type of molecular rearrangement, in the aliphatic series, is the pinacone-pinacoline conversion. But many similar rearrangements fall outside this class, for example



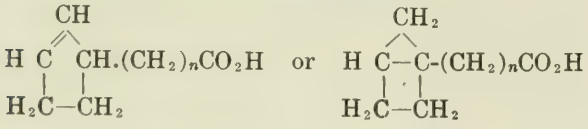
to which Tiffeneau refers as "retropinacoline rearrangements." Meerwein has recently made a systematic study of pinacones in an effort to determine the relative ease

of "migration" of different groups. So far our knowledge of these molecular rearrangements is little more than a catalogue of the facts, but it is probably not rash to hazard the opinion that our next real advance in our understanding of these facts will come not from organic chemists but from those physical chemists who are investigating atomic structures and valence.

Field for Industrial Research

There are innumerable definite subjects for investigation which would be of industrial interest and possibly valuable. Good methods for the synthesis of the higher alcohols and aldehydes are lacking. No satisfactory method for the synthesis of menthol has been developed, although the hydrocarbon paramenthane can be readily made by the hydrogenation of paracymene. We are apparently on the threshold of the chemical utilization of the simpler olefines, particularly ethylene and propylene. Large-scale development work recently carried out indicates that ethyl alcohol, acetaldehyde, acetone, glycols, chlorhydrins and chlorinated solvents will be manufactured on a large scale, probably from oil gas. The possible uses in syntheses of the reactive chlorhydrins and the corresponding oxides, such as ethylene oxide, propylene oxide, amylene oxide and the like, are many.

Petroleums offer an enormous, though difficult, field for industrial research, but the utilization of petroleum hydrocarbons in chemical ways has undoubtedly been held in check by our lack of knowledge of the non-benzenoid hydrocarbons generally. As regards the origin of petroleums it is of interest to note the recent finding of a highly unsaturated hydrocarbon, $C_{29}H_{48}F_6$ in shark liver oils. It is now fairly well established that the naphthenic acids of Russian petroleum are derivatives of cyclopentane, and Power and Barrowcliff have found similar acids in certain vegetable oils. They conclude that the optically active acids of chaulmoogra oil are also derivatives of cyclopentane,



Formation of Petroleum

Although Engler has shown that the destructive distillation of fats or fatty oils under pressure yields a mixture composed chiefly of hydrocarbons and closely resembling crude petroleum, this by no means proves that petroleums were formed in this manner. Petroleums are sometimes found trapped in undisturbed strata, free from volcanic intrusions or other source of heat, as in the Trenton limestone in Ohio, but proponents of the Engler theory state that during the long periods of geologic time these same changes may occur at much lower temperatures than those employed experimentally by Engler, a proposition naturally incapable of proof or disproof. It should be pointed out, however, that we are entirely in the dark as to how saturated hydrocarbons are formed by biochemical processes in nature—for example, normal heptane in the oleoresin of *Pinus sabiniana*, and paraffines in many essential oils, as in the common rose.

Unsaturated hydrocarbons, such as the terpenes, are conceivably formed by decomposition of terpene alcohols, which can be duplicated in many cases *ex vitro* by treating with organic acids, formic or oxalic, at very moderate temperatures. Some have claimed that anaërobic fermentations, such as would doubtless occur in organic remains under water and mud and which is commonly observed in the decomposition of cellulose to methane, furnish us with the most plausible theory of the origin of petroleum. Certain micro-organisms build up complex waxy substances, as for example the tubercle bacillus, and Reichenbach first recognized paraffine as one of the products of decomposition of organic matter. As has been pointed out by Maberry, the action of sulphur and air, or oxygen, on petroleums has probably modified them to a great extent.

As regards sulphur, Erdmann has recently shown that this element combines directly with olefines, apparently as S_3, forming what Erdmann terms thiozonides. Beyond this we know only that when strongly heated together, sulphur and heavy hydrocarbons give hydrogen sulphide and tar or coke. Friedmann's attempt to form benzene and toluene by removing hydrogen from cyclohexanes by heating with sulphur was negative. The structure of the well-known and valuable ichthyols is not known, but products closely resembling the natural Austrian ichthyol have been manufactured in this country since the Austrian supply was cut off in 1914.

Fatty Acids and Asphalts From Paraffine

The oxidation of paraffines and the non-benzenoid hydrocarbons generally by air or oxygen has been studied but little. Byerly developed his well-known process of manufacturing asphalt by air blowing the heavy petroleum residuum, and this process is apparently catalyzed by small quantities of sulphur. In this process water is formed and the product contains very little oxygen, but recent work indicates that true fatty acids can be made by the air oxidation of paraffine at about 150 deg. The latter process has probably been inspired by the desirability of manufacturing fatty acids from petroleum hydrocarbons. It is of course possible that some empirical method may be stumbled upon which will serve as a manufacturing process, but a problem of this magnitude deserves careful research of the highest order.

Unsaturated Hydrocarbons

In connection with the oxidation of saturated hydrocarbons the problem of utilizing the unsaturated hydrocarbons of petroleum distillates should be mentioned. At the present time these substances are largely lost by the present refining methods, treating with concentrated sulphuric acid, etc. With the advent of shale distillation, which is bound to become of increasing importance as the supply of natural crude petroleum dwindles, the solution of this problem will become of increasing importance. For most purposes of lubrication it is, in the opinion of some, not necessary to remove the olefines and it is established through the work of Dunston and Thole and others that olefines possess somewhat greater viscosities than the corresponding saturated hydrocarbons. Hydrogenation of such material is technically very difficult on account of the poisoning of the catalyst by sulphur, always present in such oils. It is more likely that research will indicate a method of converting these olefines into other and valuable products which can be removed from the remaining saturated hydrocarbons. They are much more readily oxidized than saturated hydrocarbons, and it is possible that the solu-

tion of the economic production of fatty acids may lie in this direction. The chlorhydrins and glycols of the higher boiling olefines have not been prepared, probably for the reason that very few of such olefines are known or have been synthesized or isolated in a pure state. The glycols would undoubtedly be solid waxes possessing valuable properties. It is fairly obvious that a great deal of careful research on pure substances is needed to further our knowledge of these hydrocarbons, such work to proceed hand in hand with, or in advance of, the industrial developments, which procedure has yielded such fruitful results in the special field of the terpenes, essential oils and camphors.

Finally, it may be pointed out that there is no collected chemical literature published which brings the chemistry of the non-benzenoid hydrocarbons together in a systematic way and in such a manner as a student may easily study it. There are a number of very excellent works on the terpenes, the largest of which, Semmler's "Die Aetherische Oele," is about eighteen years out of date. The same may be said of Aschan's "Chemie der Alicyclische Verbindungen." Both of these works are also limited to the fields indicated by their titles. Vol. I of Engler's "Das Erdöl" is largely a catalog of the hydrocarbons noted by Beilstein, and their physical properties and more important chemical properties are briefly noted. Much valuable and up-to-date material is found scattered in several lesser works, such as E. J. Parry's "Essential Oils," Gurwitsch's "Wissenschaftliche Grundlagen der Erdölbearbeitung," Gildemeister's "Aetherische Oele," Meyer and Jacobson's famous "Lehrbuch" and the like. The compilation of a volume such as that of Aschan, including the open chain hydrocarbons as well as the cyclic ones, and brought up to date would undoubtedly facilitate and induce further research and the development of new experimental methods in this field, which in some directions is comparatively neglected but potentially most rich.

British Officials to Visit Industrial Centers

The British Department of Overseas Trade has completed arrangements for the periodical dispatch of certain of its officers having specialized knowledge of particular trades to the important industrial centers of the United Kingdom in order to bring the department into direct contact with the provincial firms. The co-operation of the Association of British Chambers of Commerce and, through it, that of the local chambers of commerce have been secured.

It is planned that the visits shall be monthly and cover in each case about five days. Publicity will be given in advance of the proposed visits of officers, and provincial firms desiring an interview are expected to make application to the Chamber of Commerce in the most suitable center. The visiting officers will deal with problems connected with overseas trade possibilities and conditions and discuss as far as possible such matters as:

1. Contracts open to tender.
2. Overseas demand for particular goods.
3. Importers of various goods in overseas markets.
4. Agencies for British manufacturers.
5. General conditions obtaining in overseas markets, including:
   - (*a*) Best method of marketing and distribution.
   - (*b*) Credit conditions.
   - (*c*) Terms of payment.
   - (*d*) Nature of competition and best methods of meeting same, etc.
6. Shipping and transport.

Development of Kauri-Gum Industry in New Zealand

Since the close of war more attention has been given to the development of the kauri-gum industry in New Zealand than any time during the past five years, with the result that it seems probable that greater quantities of kauri gum and its byproducts will be produced than heretofore.

Oil From Kauri Peat Swamps

There are very extensive kauri-peat swamps in New Zealand that have been placed at the disposal of interested parties by the New Zealand Government on a leased basis. The present area which the Governor General by Order in Council may set apart for the development of this industry is 10,000 acres which may be leased for forty-two years, with no party to receive a lease exceeding 3,000 acres. The lessees have to pay a low rental and also a royalty on kauri oil and other valuable products obtained.

The New Zealand Peat Oils (Ltd.) has taken one grant of 3,000 acres, and is now developing it with reasonably good prospects of success, having tested four samples taken from different depths of the swamp which yielded an average of 29 gal. of crude kauri-gum oil to the ton, with a yield of 4,300 cu.ft. of gas per ton. This company proposes to push the development of this industry during the coming year.

Kauri-Gum Extraction and Grading

A new method of gathering and grading kauri gum has lately been undertaken, whereby kauri-peat swamps that are thoroughly pregnated with kauri gum in different stages of decomposition can be worked with reasonably good success, according to late reports. It is claimed that if this process succeeds, as indicated at present, there can be more kauri gum secured from the deposits in the North Island than has been secured to date, though of an inferior grade to that which has been gathered.

It is proposed to sort this kauri gum into about three or four grades according to size, which means largely according to the degree of decomposition. It is claimed any grade would be sufficient in quality for the manufacture of the lower grades of varnishes and similar products, and would be exceptionally good for the manufacture of linoleums and that line of goods and it is expected that these qualities of kauri gum can be produced in such quantities as to be sold for a very much more reasonable price.

Production of Kauri Gum

The production of kauri gum during the seven years previous to the beginning of the war averaged not far from 8,000 tons per year, while since that time it has scarcely averaged 4,000 tons, and during the year ended March 31, 1919, amounted to only 2,338 tons. Of the output of 8,473 tons for 1914 the United States took 4,531 tons, the United Kingdom 3,335 tons, Germany 373 tons, and the remainder was well scattered over ten other countries; while for the year ended March 31, 1919, the United States took 1,371 tons of the 2,338 tons, the United Kingdom 346 tons, Canada 572 tons, and Australia 49 tons.

Of late quite large quantities of kauri gum have been going forward to the United States as shipping space could be obtained, and there are still large quantities in hand for export.

The Chemistry of Leather Manufacture*

By Dr. James A. Wilson

THE leather business is a chemical industry, but has not been developed by chemists, although dating back to ancient times. It has been only in the last thirty-five years that the chemist has in any way been connected with the operations of leather manufacture. Up until five years ago he was called in only to settle disputes between the buyer and seller on the various chemicals purchased for the business. This condition still exists in a great many tanneries.

The chemist has not altered the fundamental principles of the industry. but he has improved upon the processes, and it may be predicted that within the next few years he will do much to change the operation entirely. There are no up-to-date books published at the present time on this branch of the industry.

Consecutive Stages in the Treatment of Hides at the Tannery

Hides are received at the tannery in four conditions—namely, fresh, salted, and dried hides, and hides that have been both salted and dried. The first operation is to soak the skins in water to remove dirt and blood and at the same time swell the fibers to a normal condition. When the hides are removed from these soaks, which require from four to five days, they contain about 80 per cent water.

They are then taken to the beam house, where everything is to be removed except the hide fibers and grain. The main mass of the hide consists of fibers with an epidermal layer containing the hair on one side. Beneath this epidermal layer is a second layer which contains the roots of the hair. In order to free the hide from hair it is soaked in a solution of lime in excess with sodium sulphide. Addition of sodium sulphide in the lime water cuts down the time of dehairing from two weeks to from one to three days. This alkali destroys the under layer of skin which holds the hair, so that when the hide is taken from the bath it may be easily brushed free by hand. The chemistry involved in this operation is supposed to be the hydrolysis of the under layer of skin. The hide fibers swell further during this process and after the hair has been scraped off and all extraneous substance removed, it is taken to the bating house. The old method of bating consisted of soaking in dung, but this has been displaced by the use of so-called bates—mixtures of sodium chloride and trypsin. While soaking in this solution the swelling caused by liming is somewhat counteracted.

Chemical Action in Tanning by the Chrome Method

If the leather is to be tanned by the chrome method a mixture of hydrochloric and sulphuric acid is added to acidify the hide before it goes to the $CrOHSO_4$ solution. This acidification is to prevent any precipitation in the chrome bath. Chemical control is exercised during this pickling process.

In chroming leather, the basicity and the chromium concentration must be correct. By far the most important factor is the content of neutral salts, that is, of ammonium chloride, lithium chloride, magnesium chloride or sodium chloride. The real chemical action consists of the formation of a chromium collagenate in the leather, by reaction between the tannin and hydroxyl group, and the resulting substance may be considered as an analogous compound to chromium acetate. If too large a quantity of the neutral salt is present, the quantity of solvent is reduced because of the hydration of this salt, which thus increases the per cent of all constituents present in solution. The test for the end of this reaction is made by placing a piece of the leather in water and boiling for five minutes, during which time no change can take place in the general visual appearance.

Vegetable Tanning

In vegetable tanning no acid or pickling bath is used, the chemical action being a combination between tannin and the amino group. One of the common tanning materials is hemlock liquor, prepared by extracting hemlock bark with water. The hide first goes through a weak solution of this liquor and gradually moves forward to solutions of increasing strength and astringency. This may be done either by changing the hide from vat to vat or by pumping in stronger liquors each time.

Of all the vegetable tanning extracts available, quebracho—secured from South America—is cheapest, most plentiful and gives excellent weight to the hide, and would ordinarily be used where the finished product is to be sold by weight. It is considered by many tanners that quebracho bark cannot be used alone in tanning because of its high astringency and that the first steps of the process must be accomplished with gambier or sumac. Experiments made by the speaker showed, however, that quebracho extract can be used without resorting to the other more expensive extracts by simply diluting with gallic acid or similar diluent.

Oiling the Hides

After the leather is tanned, either by the chrome or vegetable process, oil must be incorporated into the hides to make them pliable and tough. This is usually done by treating them with an emulsion of hot oil and water in a process called "drumming," during which the oil is taken into the hide and water forced out. This operation requires only from ten to fifteen minutes. In case of some of the heavier leathers heavy grease is rubbed into the hides. About 6 per cent of oil by weight is absorbed in the light leathers and as high as 20 per cent in the heavier leathers where the grease treatment is used. Mineral oil is necessary during the drumming operation to dissolve the solid fatty acids from the hide, while vegetable oil is necessary because it does not leave grease on the surface of finished leather. Thus a proper mixture of both is necessary to successful operation.

Microphotographs of finished leather sections show that the substance is a fibrous material. The animal source of a particular finished leather can easily be detected by magnifying a sample to ten diameters, each different kind of hide showing a distinctive appearance.

Leather chemists have much in common with the scientists at the universities, and need the co-operation of both physicists and chemists in the development of their industry. Many problems can be made available to the research department of any university desiring to enter into the subject.

A Comparative Test Upon High-Speed Steels—III

A Detailed Description of the Method of Procedure in Testing Sixteen Different Commercial Brands of High-Speed Tool Steel, Together With Data as to the Performance of Each Individual Tool, Its Chemical Composition, Heat Treatment, and Hardness*

By A. J. LANGHAMMER, M.E.†

VARIOUS steps in the preparation for a test are fundamentally important and must be carefully planned and performed to insure ultimately correct data. The essential factors are composed of the following steps, each one of which will be briefly described: First, procuring specimen bar of high-speed steel; second, making of tool; third, heat treatment of tool; fourth, grinding of tool; fifth, apparatus used and working details, and sixth, chemical and metallographic tests.

Procuring Specimen Bar of High-Speed Steel

A small order specifying the "best grade" of high-speed steel was placed with the various steel manufacturers. No mention was made of the fact that this steel was to be used for test purposes. A reasonably short time for delivery was specified. Upon receipt of shipment, each item was held for the personal attention of the man in charge of the test. After general physical inspection every bar was duly labeled and carefully stored until all the steel ordered had been received.

Making of Tool and Heat Treatment

A short piece was cut by a power hack saw (not nicked and broken) from the end of each bar and the latter then inspected at the "cut." Hereupon another piece was cut off for chemical and metallographical investigation. Finally, four pieces, each 6 in. in length, were cut for the test tools proper. Every tool was at once marked permanently with a symbol (A, B, etc.) representing the brand of steel and then stamped number 0, 1, 2 or 3 to differentiate among the tools of the brand. This designation was adhered to throughout the test and provided positive means of identification at all times as well as a concise method for comparison. The symbols chosen, too, were of such nature that they did not directly reveal the brand of the steel, which practice provides for absolute impartiality on the part of the experimenters. All the tools were then machined on a milling machine to the dimensions and tool angles indicated[1] in Fig. 2, viz: 6 deg. clearance at the nose and 10 deg. at the heel, 14 deg. side slope, 0 deg. back slope, 32 deg. horizontal clearance and 8 deg. vertical clearance, 84 deg. lip angle, and 90 deg. cutting angle. A slight cut was also taken from the base to insure a perfect seat. After machining, the tools were rough-ground to insure a minimum of finish-grinding upon hardening. All tools were then subjected to complete inspection and necessary corrections made, whereupon they were ready for hardening.

Once the tools were "made," and then only, every steel manufacturer or his representative was advised that a test was being conducted and they were given the choice of either hardening the tools themselves, having our man harden the tools under their direction, or send in their specifications for heat treatment and permit us to do the hardening without their supervision. It was understood, of course, that in each case the hardening had to be done in our plant and under constant observation. In the majority of cases the second proposal was accepted, i.e., our tool hardener performed the work in accordance with the verbal instructions of the steel companies' experts. Each representative had our entire equipment at his disposal and while he was at work no rival steel man was present. Our equipment was quite complete and the needs of each agent were easily satisfied. Every man was told that the heat treatment was the only factor he could control and that but one test of four tools could be made. He was therefore duly cognizant of the great importance of his work and was perforce extremely careful. Complete observations were made as to the methods applied and the behavior of each tool carefully noted, especially while at the high heat. A separate data sheet and discussion of the different methods of heat treatment applied are given in Table II in conjunction with the summary of chemical analysis and reproduced herewith.

Two furnaces were employed, one for the low or preheat and the other for the high heat. In each case the temperatures were adjusted to the satisfaction of the steel men before the tools were put into the furnace. Semi-muffle type oil-fired furnaces were used.

Grinding of Tool

It is generally conceded that probably more tools are spoiled through overheating in grinding than in any other way. As pointed out above under "Making of Tool," all tools were rough-machined and rough-ground before hardening, thereby reducing the chances for ruining in grinding. A high-grade tool grinder performed the work under constant supervision, and in this way the danger of overheating was minimized and the correct values of cutting angles assured. The machine used was a Taylor automatic tool grinder and particular care was exercised to see that the copious stream of cooling water provided was applied to the nose of the tool directly at the point of contact with the emery wheel. After the tools had been finish-ground, each one was inspected for flaws in the material and all cutting and clearance angles were checked. The base of each tool, in addition, was inspected for deformation, since a perfect seat in the holder is essential.

After the tools were put through the first run they were reground to the original design except that the radius at the nose of the tool was double that of the original value, i. e., $\frac{1}{16}$-in. radius on the first run and $\frac{1}{8}$-in. on the second run. Of course, in the regrind here was more chance for injuring the tools. It is felt, how-

M	0.69	16.95	0.75	0.18	3.09	None	None			Oil and kerosene.	1100	Tool 2 quenched in oil. Tools 0, 1 and 3 quenched in kerosene. "M" tools withstood the high heat very well.
N	0.66	13.55	2.20	0.10	3.59	None	None			Oil	1050	
O	0.67	13.50	0.99	0.20	4.30	None	None			Oil and lead	1100	For tool 0 only. Tools 1, 2 and 3 were not drawn.
P	0.38	15.27	0.05	0.20	2.85	None	0.14			Lead	1100	Blistered on heating.
R	0.65	17.08	0.58	0.20	2.78	None	0.10			Oil and lead	1075	Tools 0 and 2 were quenched in lead. Tools 1 and 3 were quenched in oil.
13, 14‡	0.75	11.12	2.10	0.32	5.13	None	None					

The samples for chemical analysis were obtained from the same section of the bar of which the tools were made.

The temperature of the lead bath used in quenching was maintained at a temperature of 1050 F. The tools were immersed in the molten metal for about 3 min., and then allowed to cool in the air.

* Phosphorus and sulphur below 0.04 per cent in all cases.
† The second analysis under F gives that of a second bar obtained subsequently.
‡ This steel was not tested, but its microstructure is shown in Figs. 13 and 14.

ever, that with the care and vigilance that was exercised, this possibility was eliminated.

Apparatus Used and Working Details

As stated in a foregoing paragraph, the machine tool used was a new 8-in. Lo-Swing lathe, shown[2] in Fig. 3. The general set-up is shown[3] in Fig. 1. Attention is especially invited to the particularly rigid method that is used for holding and driving the work. It is also to be observed that the set-up included but one tool block and that the tool traveled from the point shown to the dome end of the cylinder. Fig. 4 shows[4] very clearly the method of clamping the tool and attention is called to the unusual area of tool base that is clamped and supported, as compared with the ordinary lathe tool post.

When each cut was started the tool was carefully "fed in" until the proper depth of cut ($\frac{5}{32}$ in.) was reached. The tool was then fed by hand longitudinally for about $\frac{1}{4}$ in. for the purpose of checking the "turned" diameter. In this way the depth of cut was held very close—within the limits of plus or minus 0.0025 in., to be exact. Only after the correct depth of cut had been attained was the longitudinal power feed engaged (0.054 in. for first run and 0.090 in. for second), the stop watch being started at the same time. As soon as the cut was "across," the watch was stopped and the time recorded. This was repeated until the tool failed, whereupon the total time or life of the tool was at once computed by the observer, which figure was later checked in the office. All other tools were then put through the test in the same way. Whenever a tool failed in cutting, the "burned" part of the cylinder that was caused by the tool failing was turned off with a tool that was not a test specimen, thereby relieving the succeeding test tool of the handicap of cutting metal hardened by burning. In this way every test tool started to cut under identical conditions, which was especially desirable in our case because of the relatively short length of the material cut.

As a further check on the life of each tool, the actual number of cylinders machined was recorded and then compared with the total time credited to the tool.

After the life of each tool was recorded and these data checked, the results were plotted and are shown in the graphical representation on "curve sheets," reproduced in Figs. 5 and 6. The time or life of each tool was plotted as abscissæ, while the brands were indicated as ordinates. In both runs the value representing the total life of each set of tools is shown on the same sheet. It will have been noticed that each individual tool was stamped with a symbol representing the particular brand from which it was made and that the tools in each brand were numbered 0, 1, 2 and 3. By using this differentiation and referring to the data sheets on chemical analysis, heat treatment, and the curve sheets, the why and wherefore of exhibited characteristics can usually be traced quite easily. To facilitate this work, however, a series of data sheets under "Notes on Performance" have been included below.

Chemical and Metallographical Tests

It has been pointed out that a short piece was cut from each bar of steel for the purpose of procuring the chemical analysis of each brand. The work was done in the Packard laboratory and as some of the data appeared questionable, check samples were sent to a local laboratory and again to New York, each report concurring in our analysis, except in the case of uranium. Both outside laboratories reported more than 0.20 per cent uranium in brand "D" but only a possible trace in half a dozen other brands.

Several microphotographs were made and will be published later with a separate discussion. In the same

way, while Table II shows the chemical analysis, comments thereon will be given subsequently.

Table VII, giving the scleroscope hardness of each individual test tool, is included for checking purposes. It is contended that the degree of scleroscope hardness is in no way related to red-hardness, once a certain initial hardness (about 80) has been attained. In other words, if one tool registers 83 and another 88, it does not follow that there will be any difference in the cutting qualities of the two. Hardness readings should be taken of each tool after the finish grinding for the first run and used as a general indicator. The given data were secured at that time. The readings taken at the nose tip are, of course, lower in value than those of the group taken farther back on the lip surface. This is due to the fact that in the first instance the drop hammer rebounded from an overhung surface, while in the latter case the footing was solid, the heel being directly beneath the point where the reading was se-

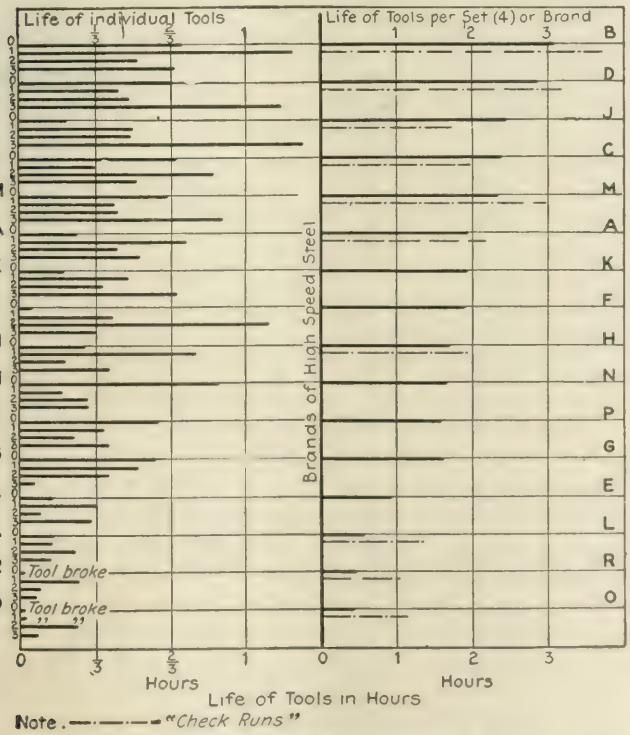

FIG. 6: CURVE SHEET OF SECOND RUN

Turning Liberty motor cylinders 5½ in. diameter. Tool with ⅛-in. radius nose; cutting speed, 35 ft.; feed, 0.090 in.; depth 3/32 in.

TABLE IV. NOTES ON PERFORMANCE OF FIRST RUN

Brand	No.	Time	No. of Cylinders	Remarks
L	0	20.6 min.	4	Dulled quickly; then failed.
	1	20 5 min.	4	Dulled quickly, then failed.
	2	47 8 min.	9	Failed slowly
	3	56 2 min.	11	Failed quickly
		Total time, 2 hr. 25 min. 6 sec.		
C	0	1 hr. 48.0 min.	21	Showed wear early but continued to cut.
	1	3 hr. 12.9 min.	38	Failed rapidly.
	2	49.0 min.	10	Failed suddenly.
	3	1 hr. 17.3 min.	15	Showed wear early but continued to cut.
		Total time, 7 hr. 7 min. 12 sec.		
A	0	1 hr. 40.4 min.	20	Tool indicated wear and then failed.
	1	2 hr. 14.5 min.	27	Failed slowly
	2	1 hr. 52 min. 42 sec.	22	Failed slowly.
	3	3 hr. 39 min. 18 sec.	44	Failed gradually.
		Total time, 9 hr. 26 min. 54 sec.		
B	0	3 hr. 40.5 min.	44	Failed very slowly.
	1	21.6 min.	4	Nose chipped.
	2	1 hr. 51.5 min.	22	Failed slowly
	3	1 hr. 56.7 min.	23	Failed after showing dullness.
		Total time, 7 hr. 50 min. 18 sec.		
O	0	4.6 min.	1	Tool broke.
	1	2.1 min.	¼	Tool broke.
	2	20.5 min.	4	Dulled quickly; then failed
	3	52.2 min.	10	Failed suddenly.
		Total time, 1 hr. 19 min. 24 sec.		
M	0	19 min. 17 sec.	4	Showed chipped cutting edge
	1	1 hr. 36 min. 6 sec.	19	Failed suddenly
	2	20 min. 56 sec.	4	Showed slightly chipped cutting edge and failed quickly
	3	7 min. 15 sec.	2	Failed quickly.
		Total time, 2 hr. 23 min. 34 sec.		
H	0	1 hr. 21 min. 30 sec.	16	Failed slowly
	1	56.0 min.	11	Uniform wear
	2	47.0 min.	9	Failed quickly.
	3	1 hr. 39 min. 38 sec.	20	Failed slowly.
		Total time, 4 hr. 44 min. 8 sec.		
K	0	31 min. 14 sec.	6	Dulled quickly
	1	46 min. 49 sec.	9	Failed suddenly.
	2	34 min. 56 sec.	7	Nose chipped slightly but continued to cut.
	3	44 min. 14 sec.	9	Failed quickly.
		Total time, 2 hr. 37 min. 13 sec.		
J	0	1 hr. 6 min. 28 sec.	13	Failed slowly
	1	19 min. 8 sec.	4	Dulled, then failed quickly.
	2	27 min. 36 sec.	5	Dulled, then failed rapidly.
	3	1 hr. 20 min. 5 sec.	16	Failed quickly
		Total time, 3 hr. 13 min. 17 sec.		
D	0	2 hr. 29 0 min.	30	Failed slowly
	1	1 hr 37.3 min.	19	Failed slowly
	2	59 0 min.	12	Failed gradually.
	3	1 hr. 55 9 min.	23	Failed slowly
		Total time, 7 hr. 1 min. 12 sec.		
P	0	4.2 min.	1	Failed quickly.
	1	24 9 min.	5	Dulled early
	2	6.4 min.	1	Failed quickly
	3	36.0 min.	7	Failed suddenly
		Total time, 1 hr. 11 min. 30 sec.		
N	0	23.0 min.	4	Dulled quickly but continued to cut.
	1	25.8 min.	5	Failed quickly.
	2	44 1 min.	9	Failed slowly.
	3	18 3 min.	4	Showed wear, then failed.
		Total time, 1 hr. 51 min. 12 sec.		
R	0	3 4 min.	1	Nose broke.
	1	9 8 min.	2	Failed quickly.
	2	0 8 min.	0	Failed quickly
	3	27 3 min.	5	Failed gradually
		Total time, 41 min. 18 sec.		
E	0	1 hr. 44.0 min.	21	Failed quickly
	1	52 3 min.	10	Failed rather slowly
	2	1 hr. 58.9 min.	24	Failed slowly
	3	2 hr. 24 0 min.	29	Failed slowly
		Total time, 6 hr. 59 min. 12 sec.		
F	0	2 hr. 45.8 min.	33	Failed slowly
	1	1 hr. 36 3 min.	17	Chipped but continued to cut
	2	55.5 min.	11	Failed quickly
	3	1 hr. 38.8 min.	20	Showed wear early
		Total time, 6 hr. 56 min. 24 sec.		
G	0	1 hr. 8 1 min.	14	Showed wear but continued to cut
	1	1 hr. 55.6 min.	23	Failed slowly
	2	1 hr. 33 1 min.	19	Cut roughly but held its size
	3	19 3 min.	4	Failed quickly.
		Total time, 5 hr. 54 min. 6 sec.		

TABLE V. NOTES ON PERFORMANCE OF SECOND RUN

Brand	No.	Time	No. of Cylinders	Remarks
C	0	41 min 42 sec	10	After 30 min. 54 sec., rapid wearing was apparent though the tool continued to cut.
	1	19 min 13 sec	5	Failed suddenly.
	2	51 min 36 sec	12	Showed wear three minutes before failure occurred.
	3	33 min 12 sec	8	Failed gradually.
		Total time, 2 hr. 25 min. 43 sec.		
N	0	53 min 30 sec	14	Failed suddenly.
	1	11 min 24 sec	3	Showed wear after the second cylinder.
	2	18 min	4	Failed slowly.
	3	18 min 18 sec	5	Failed slowly.
		Total time, 1 hr. 41 min. 12 sec.		
E	0	9 min 12 sec	2	Tool indicated dullness and then broke.
	1	20 min 30 sec	5	Failed gradually.
	2	5 min 24 sec	1	Tool broke.
	3	19 min 48 sec	4	The nose chipped after 4½ min., but continued to cut, though irregular.
		Total time, 54 min. 54 sec.		
O	0			Broke on first run.
	1			Broke on first run.
	2	15 min 30 sec	4	Dulled quickly but continued cutting and then failed suddenly.
	3	4 min 30 sec	1	Tool broke.
		Total time, 20 min.		
M	0	38 min 30 sec	9	Failed very slowly.
	1	25 min 22 sec	6	Failed suddenly several minutes after showing wear.
	2	26 min	7	Tool broke.
	3	54 min	14	Failed suddenly.
		Total time, 2 hr. 22 min. 52 sec.		
P	0	37 min	9	Failed slowly.
	1	22.5 min	5	Failed rapidly after becoming dull.
	2	14 min	4	Failed suddenly.
	3	24 min 48 sec	6	Failed gradually after first indication of dullness.
		Total time, 1 hr. 38 min. 18 sec.		
G	0	36 min 18 sec	9	Showed wear 1 minute before it failed.
	1	32 min 18 sec	8	Failed gradually in last 3 minutes.
	2	24 min	6	Failed slowly.
	3	3 min 36 sec	1	Tool broke.
		Total time, 1 hr. 36 min. 12 sec.		
H	0	17 min 42 sec	4	Grew dull 4 minutes before failure.
	1	47 min 6 sec	9	Failed very slowly.
	2	12 min 54 sec	3	Began to dull on the second cylinder.
	3	24 min 36 sec	6	Failed suddenly.
		Total time, 1 hr. 42 min. 18 sec.		
A	0	15 min	4	Nose chipped slightly after seven minutes running, then failed gradually.
	1	44 min 12 sec	11	Failed very slowly after first indication of dullness.
	2	26 min 30 sec	6	Failed gradually in the last four minutes.
	3	31 min 6 sec	8	Gave indication of dullness eight minutes before failure.
		Total time, 1 hr. 56 min. 48 sec.		
L	0	8 min 35 sec	2	Dulled quickly, wear increasing rapidly until failure occurred.
	1	8 min 12 sec	2	Failed slowly.
	2	14 min 6 sec	4	Showed wear on second cylinder but failed slowly.
	3	7 min	2	Failed gradually after the cutting edges chipped slightly.
		Total time, 37 min. 54 sec.		
B	0	43 min	11	Failure extremely slow after showing initial dullness.
	1	1 hr. 13 min	18	Failed suddenly.
	2	30 min 15 sec	8	Failed slowly.
	3	40 min 30 sec	10	Failed very slowly after first signs of dullness.
		Total time, 3 hr. 6 min. 46 sec.		
J	0	12 min 30 sec	3	The nose of the tool broke off while feeding across.
	1	30 min 48 sec	8	Failed rapidly after indicating wear.
	2	29 min 42 sec	7	Showed wear two minutes before failure occurred.
	3	1 hr 14 min	18	Gave indication of wear, the nose of the tool breaking while the power feed was engaged.
		Total time, 2 hr. 27 min.		
R	0			Tool broke when feeding in by hand to the proper depth.
	1	15 min	4	Grew dull soon after the start.
	2	5 min	1	Failed rapidly
	3	4 min 12 sec	1	Failed rapidly
		Total time, 24 min. 12 sec.		

TABLE V. (Continued)

Brand	No.	Time	No. of Cylinders	Remarks
K	0	11 min 48 sec	3	Failed suddenly.
	1	28 min 48 sec	7	Became dull and failed within one minute.
	2	22 min 12 sec	6	Failed six minutes after the first signs of wear.
	3	42 min 30 sec	10	Failed very slowly.
		Total time, 1 hr. 43 min. 18 sec.		
D	0	47 min	12	Failed very slowly.
	1	26 min 42 sec	7	Failed very slowly.
	2	29 min 18 sec	7	Failed gradually.
	3	1 hr 10 min	17	Gave indication of wear 35 minutes before failure occurred. Almost impossible to ruin the tool as it continued to cut while at a high red heat.
		Total time, 2 hr. 53 min.		

A marked characteristic of this steel is the tendency to dull quickly but continue to cut. It is also very difficult to "burn," and cools quickly after the cut is finished.

Brand	No.	Time	No. of Cylinders	Remarks
F	0	2.4 min	1	Tool broke.
	1	25 min	6	The nose of the tool broke but continued to cut for ten minutes before failing.
	2	1 hr 7 min	17	The nose of the tool chipped after 15 minutes.
	3	20 min	4	Dulled quickly but continued to cut.
		Total time, 1 hr. 54 min. 24 sec.

cured. It will be noted that in general the hardness varied from 75 to 85, or within 10 points.

(Part IV, the last of the series, will be published in our next issue.)

Legal Notes

By Wellington Gustin

Reliability of Trade Journal Quotations in Trade Contracts

On appeal to the Supreme Court of Washington, the Trans-Pacific Corporation has been able to have the judgment obtained against it by the Marden, Orth & Hastings Corporation reduced from $15,680 to $13,440. The reduction is due to the difference in the market price of Manchurian pressed soya bean oil. The lower court had found that the breach of the contract for sale of said oil had occurred on April 11, 1918, while the Supreme Court determined the date to have been Feb. 19, 1918.

The action arose out of a contract between the parties for the delivery of 400 long tons of the soya bean oil. The contract of sale, under date of November, 1917, called for a price of $14.25 per 100 lb., the oil to be shipped immediately from the Orient and delivered c.i.f. (cost, insurance, and freight paid) at Seattle, Washington. The oil in due course should have arrived in Seattle in about four weeks. The contract was made through Horace J. Holley & Co., brokers, and payment was to be made upon arrival of the oil at Seattle.

After making the contract the Trans-Pacific Corporation requested and obtained from the purchaser corporation a letter of credit of $130,000 issued by the Equitable Trust Co. of New York. This was done as a matter of accommodation by the purchaser to aid the seller in procuring and shipping the oil from the Orient, so as to hasten delivery. The letter of credit referred to the shipment of oil as f.o.b. Seattle, when it ought to have been c.i.f. Seattle. This error, however, was corrected within a few days at the request of the seller. But some delay was occasioned thereby in furnishing the letter of credit as requested, which the seller claimed was an excuse for its failure to deliver the oil as contracted for, the price of oil advancing in the meantime.

There was nothing in the contract indicating that the purchaser was to furnish any letter of credit to aid the seller in procuring the oil in the Orient. Further, there were negotiations subsequently between the parties and an extension of time was mutually agreed upon for delivery of the oil. Hence this excuse for failure to deliver was unavailing.

Holding of Court as to Date of Breach of Sale Contract

The Supreme Court fixed Feb. 19, 1918, as the date for breaching the contract by the seller, because the purchaser had notified the latter by letter that, unless some definite advice be had as to delivery of the oil by that date, it would buy the quantity contracted for in the open market and charge the difference in price to the seller. The seller made no response to this letter and the purchaser wrote other letters demanding damages for failure to deliver the soya oil. Finally the seller wrote the purchaser, April 11, declining to accede to its demands. This date was fixed upon by the trial court as the date for breaching the contract when the market price of the oil was 16c. per lb. in Seattle. But the Supreme Court held that the purchaser's letter fixed the date as of Feb. 19, when it gave notice that it would go into the open market and buy. The price of the oil at this date was 15¾c. per lb., which marks the reduction in the judgment rendered.

Legal Validity of Trade Journals' Market Quotations

Finding a proper market price for determining the damages resulting upon a breach of a sales contract is often a difficult matter. Market quotations in recognized journals and trade papers have become acceptable to the courts in finding values, and this results in a great advantage to business men and to trade and industry. Men may contract with reference to such quotations, and have a ready basis for determination of their losses and gains.

In the instant case the market value of soya bean oil at Seattle was established by quotations from a trade journal. Appealing from the trial court's ruling admitting several issues of the journal in evidence, counsel for the seller contended such market reports were too unreliable to be received as evidence. The Supreme Court held that, since other evidence showed the journal to be one of repute, and its quotations of market prices of oils, including soya bean oil, to be accepted by the trade generally throughout the United States as reliable and trustworthy, the journal was properly received in evidence.

The general rule as to the admissibility of such evidence to show market value of standard commodity of merchandise was quoted by the court as follows:

"It is a rule recognized generally that market reports or quotations as contained in newspapers, trade journals, trade circulars, price lists, etc., are competent evidence of the state of the market. Indeed, such reports, based as they are upon a general survey of the whole market, and constantly received and acted upon by dealers, are far more satisfactory and reliable than individual entries or individual sales or inquiries, and courts would justly be subject to ridicule if they should deliberately shut their eyes to the sources of information which the rest of the world relies upon, and demand evidence of a less certain and satisfactory character. Such evidence is within an exception to the general rule barring the admission of hearsay evidence inasmuch as it comes from a public authentic source which is deemed to give it reliability."

No Liability if Experienced Employee Chooses Unsafe Methods

In case of negligence brought by an employee against the Monroe Oil & Fertilizer Co. a judgment in favor of the company has been affirmed in the Georgia Court of Appeals. The evidence shows that the plaintiff employee undertook to put a belt on a rapidly revolving pulley, and was injured in so doing. It also appears that the employee had a choice of two ways of putting the belt on the pulley, one a safe way and the other a dangerous one. Both of these ways were known to the employee and he chose the dangerous way.

The employee having selected the dangerous way, he cannot recover of the employer for his injuries thus sustained, although his conduct in selecting that way may not have amounted to actual rashness, said the court.

The Galvanometer*

By E. F. Northrup

BY MEANS of instruments we learn that certain forces in nature are active and energy transformations are in progress, the very existence of which would otherwise remain forever hidden because they affect no sense of the living organism. Thus instruments are required for the detection of the feeble electric currents which circulate in the soil, or the magnetic field of the earth, or the radio-active transformations of slowly disintegrating matter, or Roentgen rays, or ultra-violet radiation, or long electromagnetic waves. These forces and many others excite no response in the living organism, which is unprovided with senses for their detection. (One may here suggest that perhaps Sir Oliver Lodge, or his associates, will yet devise an instrument which will be sensitively responsive to disembodied spirits when they make a near approach. The invention would be welcome because the five senses of most people seem disappointingly inadequate for giving informing knowledge!)

The facts are that the history of the acquisition of modern scientific knowledge in all its branches is closely paralleled by the history of the invention and the perfecting of scientific instruments; instruments which reveal existences in nature to which none of the five senses is even qualitatively responsive, and a multitude of other instruments which aid and supplement the senses by immensely extending their range.

If, in some museum of high repute, a Hall of Fame should be established wherein would be gathered, and historically grouped, typical examples, held worthy of admission, of all scientific instruments of investigation, an observer would have before his eyes the entire history of science from the days of Gilbert, or of astronomy from the days of Tycho Brahe. In this Hall of Fame in prominent setting would be seen the galvanometer. Beneath it would be placed a large card on which would be printed the fascinating story of the wizard-like achievements of modern electrical science, alone made possible because of the invention of this wonderful little instrument.

Discovery of the Galvanometer

The real discoverer of the galvanometer was Oersted, when in 1820, only one hundred years ago, he noted that a compass needle placed close to a wire transversed by the electrical current set itself at *right angles* to the wire. Here was discovered a new force entirely unique, and an instrument absolutely new was invented. This force could never have been noted if man had worked with his five senses only.

All galvanometers constructed from that day to this depend for their action on this observation made by Oersted. In some instruments the wire which carries the electric current is stationary and a delicately suspended magnetic needle is allowed to turn. In another class of instruments the wire which carries the current is wound up into a coil and this coil is delicately suspended and turns in the field of force supplied by a massive magnet, itself held stationary. Thus galvanometers are divided into two general classes: moving-magnet and moving-coil galvanometers, but both groups operate alike obedient to the forces discovered by Oersted.

The moving-magnet galvanometer was brought to a high state of development and given astonishing sensitivity by the then Sir William Thomson. Due to his invention of this marvelously sensitive detector of feeble electric currents, the successful registering of signals sent over the first transatlantic cable was made possible. To it we owe, in truth, the first realization of practically instantaneous communication between the two worlds on the opposite sides of the Atlantic.

The Moving-Coil Galvanometer

The moving-coil galvanometer has no single achievement so brilliant as this in its record, because it can be made only a fifth or a tenth as sensitive as the moving-magnet form. It is, however, a far more convenient and less erratic instrument to work with, and for this reason has taken its place, in preference to the more sensitive moving-magnet galvanometer, as the most used of scientific tools in every laboratory of physical research and instruction throughout the world. When this instrument is supplemented with current-carrying shunts, currents of the greatest magnitude producible—20,000 amp. or more—can be measured, and yet this simple instrument when designed to peer, as it were, into the micro-cosmic world can detect the existence of an electric current too small for the imagination to conceive. Thus a moving-magnet galvanometer, with good working qualities and designed for very moderate sensibility, will give a millimeter deflection on a scale one meter from its mirror when 188×10^{-9} amp. flows through its coil. This figure means nothing to the mind unless translated into an idea which in some measure can be conceived. Thus the current which this galvanometer will easily measure bears the same relation to an ampere, which is about the current used to operate a large incandescent lamp, as do 240 centimeters to the diameter of the earth.

The moving-coil galvanometer has received at the hands of designers protean forms and has been made to meet the most varying requirements. No single instrument can fill all the requirements of a laboratory of instruction or the exacting demands of research. Certain features, however, have come to be recognized as useful embodiments in any instrument of this type. Among features which I judge to be generally desirable may be listed the following:

Extreme Simplicity of Construction

Most laboratories make use of many galvanometers and simplicity of construction enables the instruments to be manufactured at low cost so many can be purchased. Then, too, those unfamiliar with the handling of galvanometers will much more readily acquire skill in handling an instrument of good performance but simple construction than they would one of slightly better performance obtained at the expense of refinements secured by more elaborate construction.

Moving Parts Visible

It is a great convenience to have the entire moving system of the galvanometer plainly exposed to view. The instrument is much more readily leveled up and when using the instrument to detect when a Wheatstone bridge or other instrument is balanced, it is convenient to be able to make preliminary adjustments by observing the movements of the coil itself, re-

*From Pyrolectric Bi-Monthly Bulletin No. 11.

ferring to the spot on the scale only when the adjustments grow close.

Protected Suspensions

The upper suspension of a galvanometer is readily broken and the lower spiral suspension becomes easily tangled. The upper suspension should therefore be attached to a delicate spring at its upper end so that a slight pull on the suspension will only stretch the spring and not break the suspension. The lower, spirally wound, suspension should consist of a long spiral not easily tangled.

Adjustment to Zero

The adjustment of the moving coil to bring the no-current reading to the zero of the scale should be easily effected; a touch of the forefinger on the adjusting device should do this.

Good Working Parts

The rotating parts should be so proportioned that without loss of sensitivity the galvanometer will reach a full deflection in from two to three seconds.

Sensitivity

It is a frequent error to adjust a galvanometer to a far higher sensitivity than the nature of the work requires. A sensitivity of ½ megohm for each ohm of coil-resistance will more than meet general requirements. High sensitivity obtained at the expense of an unstable zero reading is always to be avoided.

Coil Clearance and Stability

The inexperienced find usually extraordinary difficulty in setting up and operating a galvanometer which possesses a very small coil clearance. The slight advantage of extra sensitivity obtained by making the coil clearance very small is wholly offset by the practical difficulties in setting up and operating the instrument. The accidental passage through the coil of a large current is sooner or later likely to happen and provision should be made to prevent in this case the coil from spinning several times around, thus twisting up its suspensions.

Galvanometer Mounting

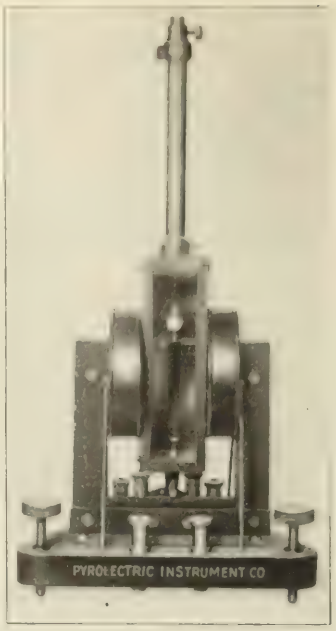
The instrument should be so designed that, with little trouble in effecting the change, the galvanometer may be mounted either on a wall or on a stand to be used on a bench or table.

Alternating Current Galvanometers

The alternating current galvanometer, such as illustrated, while primarily designed for use with alternating currents, is extremely valuable for several classes of work in which the direct current galvanometer is ordinarily employed. The following applications are pertinent:

1. For the accurate measurement of the resistivity or conductivity of salt solutions and other electrolytes.

Various devices have been employed for measuring the resistivity of electrolytes, using the Wheatstone bridge method and an alternating current as a measuring current. Among these devices the instrument most used as a detector is the telephone receiver. The a.c. galvanometer may, however, be substituted for telephone receiver to very great advantage.



A. C. GALVANOMETER

2. For the measurement of the resistivity of molten salt.

This may be done by a method not essentially different from that described by Northrup & Sherwood in the *Journal of the Franklin Institute* for October, 1916, in a paper entitled "New Methods for Measuring Resistivity of Molten Materials; Results for Certain Alloys." The above-mentioned paper describes a method in which a "resistometer" is used in conjunction with an a.c. galvanometer and Kelvin double bridge.

3. For the measurement of resistivities of molten metals. Metals in a molten state and at a high temperature invariably develop parasitic emf.'s where the potential terminals are located, and thus preclude the use of direct currents when measuring resistivities by the Kelvin double bridge method. By using alternating currents and an a.c. galvanometer their resistivities are easily measured. See numerous papers by the writer, in *Journal of the Franklin Institute.*

4. For the measurement of any resistance in which small irregular emf.'s exist.

By the use of an a.c. galvanometer and an alternating current, the resistance of a circuit or portion thereof containing a thermal emf. or even small battery emf.'s is measured as readily as a resistance free from these emf.'s is measured by using direct current and an ordinary d.c. galvanometer.

5. For high sensitivity direct current characteristics.

When the field coils of this instrument are excited with direct current, the sensitivity obtained is dependent on the strength of the field current. It is possible to produce a sensitivity of measurement (either current or voltage sensitivity) with this instrument that is unattainable with other instruments.

The writer prefers the a.c. galvanometer for all classes of resistance work and uses it invariably in his own laboratory.

The Potash Deposits of Germany

The potash deposits of Germany, which were discovered by the Prussian Government in 1843 at Stassfurt while boring for rock salt and which occur in upper layers of rock salt in the plains of northern Germany, have been estimated to occupy a volume of 10,790,000,000 cu.m. and to contain 20,000,000,000 metric tons of potash salts, corresponding to about 2,000,000,000 metric tons of potash (K_2O), a quantity sufficient to supply the world for 2,000 years at the present rate of consumption. These beds, according to the United States Geological Survey, Department of the Interior, were first exploited about 1860, and have furnished practically the entire world's supply of potash for many years.

New Process of Japanning

Baking japan as ordinarily used in manufacturing consists of two elements, the base and the solvent. The base is usually some variety of asphalt, combined with linseed or some similar oil, the whole making a hard rubbery-appearing substance. This must be liquefied for use, and the common practice is to dissolve it in naphtha or kerosene. The process of japanning various metal articles consists in dipping them in the liquid japan, and then baking them in an oven.

Owing to the volatile and inflammable type of the solvents used, this baking process is somewhat hazardous. After several bakings have been consummated, the atmosphere in the oven resembles that of the inside of a gasoline engine cylinder, only needing a spark, or even excessively high temperature, to cause an explosion of great force. Occasionally the results of these ovens blowing up have been disastrous, due to losses from fires, caused by the explosion.

Non-Combustible Japan Solvent

The manufacturers consequently became interested in the possibility of developing a type of japan which has a non-combustible solvent. The Research Laboratory of the General Electric Co. was requested to try to evolve such a product, and a course of research resulted in the development of a variety of japan which eliminated the necessity of a solvent possessed of the destructive propensities of the conventional kinds.

This water japan, as it is called, is an emulsion of the asphalt oil base with water. By this is meant that infinitesimal particles of the base are held in suspension in the water, instead of being dissolved in it. It was found that this japan had no tendency to settle out, even after months of storage, and that, owing to its being "suspended" in water, losses by evaporation were practically negligible.

Methods of Japanning

The methods of applying the japan are two in number: the electric dip and the hot dip.

The first method, or the electric dip, which is the most appropriate for small articles, consists in placing them, charged positively, in a negatively charged iron tank of japan. The result is that an even, smooth coating of japan is deposited on the articles in question, and, since the japan is deposited free from solvent, there is no resultant drip when the lot is conveyed to the baking ovens.

The second method, or the hot dip, which is applicable to large pieces of metal, was found more or less by chance. It has been the custom in the laboratory to pre-heat the metal before dipping, in order to free it from dirt and grease. This pre-heating evidently had the same effect of causing the japan to form a deposit on the metal as the giving to it of a positive electrical charge would have.

A third method is also sometimes used which is a combination of the two already mentioned; that is to say, the metal to be japanned is both heated and positively charged.

The result has been that a variety of japan has been evolved that gives exactly the same effects as the solvent variety. It is cleaner to handle, owing to the absence of drip, and eliminates the danger from explosions and disastrous fires that were such an unpleasant feature of the old form of this highly necessary compound.

Apparatus for Rapid Determination of Moisture

A labor-saving weighing device for determining the amount of moisture in a sample of paper, coal, glue, dye, soap, etc., has recently been brought out on the market by the Williams Apparatus Co. of Watertown, N. Y.

The apparatus consists of a double-walled electric oven with thermostatic control. Torsion balances accurate to 0.1 per cent, with weighing pan so constructed that the sample can be weighed either outside or inside the oven, is situated on top of the oven. The beam of the balance is designed so that the percentage of moisture can be read directly, thus eliminating all calculations.

To determine the percentage of moisture in a sample, set the thermostat to hold the temperature at the desired point. Temperature of the oven is then read from a thermometer inserted through the side. After constant temperature has been obtained, adjust the balance to equilibrium by means of tare weights, and weigh sample in the usual manner. Place the weighed sample on a weighing pan in the oven and allow it to remain until balances no longer register a loss. Again bring balances to equilibrium by means of sliding weight on beam. The sample is then at constant weight and the percentage of moisture is used directly. The time required is usually about ten minutes. Separate pans are provided so that several samples may be drying at the same time.

The advantage of such a mechanism in control work over the old method of weighing is self-evident, when one considers the considerable amount of time lost by the old method in weighing, using a dessicator, cooling, reweighing, and then repeating the process until a constant weight is finally obtained.

Power Hammer for Pulverizing Pig-Iron Samples

The time and labor required for pulverizing samples of pig iron for analytical purposes can be greatly reduced by the use of a Fairbanks power hammer, which the United Hammer Co., Boston, Mass., has designed for laboratory use. Pieces of pig iron ½ in. to ⅝ in. diameter can be pulverized in two or three minutes so that particles are fine enough to pass an 80-mesh sieve.

In one plant where this machine was installed it formerly required the labor of three men with 26-lb. sledges for twelve minutes to reduce ½-in. cubes to a sufficient degree of fineness. By the use of the power hammer the labor of two men was dispensed with and the time of the operation reduced from twelve minutes to two minutes.

The Fairbanks machine is built in two types, either belt- or motor-driven, with a 100-lb. weight of ram and 2-in. mortar and pestle. The advantages of the machine are simplicity of operation, the fact that it is under control of the operator at all times and that it is capable of striking a blow of about 600 lb. when running at 300 r.p.m.

Synopsis of Recent Chemical & Metallurgical Literature

Infusorial Earth Industry.—The results obtained during fifteen years of research and practical work by A. BIGOT, on infusorial earth, are described in the February, 1920, issue of *Revue de l'Ingénieur et Index Technique*, pp. 301-326. After giving some information on the raw material, its formation and geographic distribution, he describes and illustrates diagrammatically the influence of heat on its properties. Thus: The porosity increases with the temperature, but its aspect and volume remain the same up to about 700 deg. C. (1,290 deg. F.). Above 700 deg. C. (1,290 deg. F.) and especially beginning with 1,000 deg. C. (1,830 deg. F.) the shrinkage is very pronounced, the density rising from about 0.5 to about 2.2. The vitrification point and temperature of fusion vary between 1,300 and 1,600 deg. C. (2,370 and 2,910 deg F.) according to its chemical composition. The higher the percentage of silica the higher the melting point.

M. Bigot describes and illustrates its main properties, especially its power of absorbing gases and liquids, and its hardness. It is also sound-proof and a heat-insulator. These properties contribute to the great variety of its industrial applications, among which the most important are:

(1) As oxidizer and antiseptic used for bleaching, disinfecting and purifying.

(2) To precipitate gelatinous, colloidal or albuminous matter, in sugar refineries, breweries, distilleries, wineries, or oil refineries.

(3) To absorb liquids, when it finds convenient applications in the manufacture of dynamite, as a disinfectant, a fine abrasive, in fertilizers, in paints, in pharmaceutics and perfumery.

(4) As a sound insulator it can be used in the form of powder, granules or bricks. Taking the sound-insulating property of air as unity, that of a 0.5 density infusorial earth would be about 500.

(5) For light building construction.

(6) As heat and cold insulator, when it is used mainly as insulating material in the construction of industrial furnaces and refrigerators.

Resistance of Steels to Machining.—An explanation of the fact that some steels of a given tensile strength cannot be machined with tools which can be used for steels of higher tensile strength based upon the supposition that tensile strength at the neck is directly proportional to the cutting hardness is advanced by CH. FREMONT in a note presented at the March 1 meeting of the French Academy of Sciences (*Comptes Rendus*, vol. 170, No. 9, pp. 513-514). He cites the case of a steel of tensile strength of 78 kg. per sq.mm. (111,000 lb. per sq.in.) which could not be machined by a certain tool, whereas another steel of tensile strength of 121 kg. per sq.mm. (172,000 lb. per sq.in.) was readily cut by the same tool. If, instead of figuring the tensile strength of the steel on the basis of the original cross-section of the test piece, the ultimate strength be calculated on the basis of net section of the test piece at rupture, more concordant results may be expected. Thus the above-mentioned two steels of tensile strength of 78 and 121 kg. per sq.mm. have in reality a final tensile strength on the net section of 195 and 165 kg. per sq.cm., by which fact the author explains why the given tool could act on the second and not on the first steel.

Influence of Cadmium on Brass.—In the November-December, 1919, issue of the *Revue de Métallurgie*, LEON GUILLET gives a description of the influence of cadmium on brass. The study is timely because the greater part of zinc from western United States contains cadmium in varied amounts. He worked on brasses composed of electrolytic copper, belgian zinc (Vieille Montagne) which is free of cadmium, and metallic cadmium.

The first series of alloys he prepared contained copper 70 per cent, zinc 30 to 25 per cent and cadmium up to 5 per cent. These were submitted to mechanical tests and metallographical studies both before and after the mechanical tests. He gives tables of the different alloys he made and their behavior.

The tests show that:

(1) Up to 0.74 per cent Cd the tensile strength, elongation, resiliency and hardness are not affected.

(2) With 1.67 per cent Cd the elongation diminishes, the alloy becomes brittle and the hardness is somewhat increased.

(3) With 1.92 per cent Cd tensile strength is low, the elongation very small, the resiliency (Charpy impact) low.

(4) With 4.11 per cent Cd the tensile strength becomes insignificant.

The main conclusions to which he arrived are:

One per cent cadmium in brasses with 70 to 60 per cent copper has no appreciable effect.

A cadmium content of more than 1 per cent has a detrimental influence, especially on resiliency.

The changes in the mechanical properties of the brasses are due to the cadmium being present in a free state in the alloys.

Electric Steel Furnaces in Australia. — According to a recent article in the *Industrial Australian*, the manufacture of electric steel has been in operation for some time in Australia. The first plant erected was that of Australian Electric Steel, Ltd., at Alexandria, Sydney, comprising two furnaces of the Electro-Metals type, each having a capacity of two tons. The plant is equipped with all the usual appliances for foundry work, and castings have been turned out in considerable variety for special purposes. Ingots have also been supplied ranging in size from 4 in. square up to 24 x 12, and some of these have already been used for the forging of railway axles with successful results.

In Victoria an important step was taken last year by the Railway Commissioners toward introducing electric furnaces at the Newport shops, when three members of the staff of the Railway Department were sent to America and Canada for the purpose of making inquiries and securing all the information necessary to enable a furnace to be installed. An ample supply of cheap electric current will soon be available for use at Newport from the Department's own power house, and it is desired to take advantage of this fact to supply the demands of the railways for high-grade steel castings.

The Victorian Iron Rolling Co., of Melbourne, is also installing a plant for the production of high-grade steel. In this case the furnace will have a capacity of six

tons, and it is expected to produce about 30 tons of steel per day. The electric current is to be obtained from the Melbourne City Council's mains, and the plant will be in operation within the next few months. In the Newcastle district another company, the Commonwealth Steel Products Co., is about to commence operations. This firm is now erecting a complete plant for making electric steel, rolling tires and forging railway axles, close to the Waratah railway station. The plant is now being erected, and the furnace will use scrap steel. It will derive its current from the Newcastle City Council's supply, and will require 1,500 hp. to operate it. Special interest attaches to the tire mill, which is of a type used extensively both in America and in England, but is the first of its kind to be installed in Australia.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Manganese and Its Alloys.—Manganese or manganese alloys, low in carbon and silicon, are obtained by oxidation of a manganese alloy comparatively rich in silicon, for example, one containing more than 20 per cent of manganese and more than 10 per cent of silicon, by means of air or oxygen with or without manganese oxides or lime. The production of silicomanganese and the oxidation of the silicon may be effected in the same furnace or in successive furnaces, or ordinary silicomanganese may be mixed in the solid state with the oxidizing agents and the mixture heated to the necessary temperature, or molten silicomanganese may be bessermerized in a basic neutral or acid-lined converter with or without the addition of lime or manganese oxides, or a raw manganiferous material may be reduced with carbon in such a way as to form a manganese silicide which is thereafter oxidized. A similar procedure is used for the production of chromium and its alloys. (Br. Pats. 135,186 and 135,187—1919. AKTIEBOLAGET FERROLEGERINGAR 1, Stockholm; Jan. 21, 1920.)

Treating Fibrous Materials.—Straw, wood, flax, jute and other vegetable fibrous materials are boiled in water with a mixture of one to four parts chalk or other form of calcium carbonate and one part of an alkali compound of low causticity, such as sodium sesquicarbonate, to produce fibers suitable for spinning, for yarns, or for rope making, or to obtain a paper-making material. The residual liquor or the paste settling from it may be used as a detergent with or without the addition of sodium carbonate or soap. (Br. Pat. 135,240—1919. AMBER SIZE & CHEMICAL CO., London, and C. WEYGAN, Maidenhead, Berkshire; Jan. 21, 1920.)

Catalysts.—Catalysts, more particularly for use in the hydrogenation and dehydrogenation of organic substances, are prepared by heating (while excluding air and without the introduction of a reducing agent) an organic salt of a catalytic metal capable of producing hydrogen, for example nickel formate or oxalate, or a mixture of salts such as sodium formate and nickel sulphate. Acetates and lactates may also be used. Other catalytic metals are cobalt, iron, copper, manganese and cerium. The organic salt may be mixed with a substance which will form a support for the catalyst, and will be either inert or adapted to modify the activity of the catalyst or the cause of the reaction. Examples of such additions are infusorial earth, silica, boric acid and the carbonates, formates, and oxalates of the alkali, alkaline earth and earth metals. As a support there may also be used a metal, preferably the same as the catalytic metal in the form of wire, strip, sheet or cloth, the organic salt or mixture of such salts being either pasted on or formed either directly or indirectly on the surface portions of the metal support. (Br. Pat. 135,510—1919; A. BROCHET, Montereau, France; Jan. 28, 1920.)

Purifying Oils, Fats and Fatty Acids.—Fatty acids and their glycerides, especially fish oil and fats, are purified and deodorized by heating, admixture with a porous and powdered substance such as kieselguhr, and treatment with a non-oxidizing gas or a non-aqueous vapor such as petroleum ether or ethyl acetate. (Br. Pat. 135,295—1919. G. CALVERT, Elmhurst, Middlesex; Jan. 21, 1920.)

Vaccines. — Detoxicated vaccines are prepared by dissolving bacteria in alkali and reprecipitating with acid, the process being repeated until the supernatant liquid gives no precipitate with picric acid. As a modification the first precipitate may be washed with a solution of NaH_2PO_4 or other weak acid to remove toxins. The precipitate obtained by either method is either dissolved in alkali or mixed with a solution of NaH_2PO_4 for use. (Br. Pat. 136,036—1919. D. THOMSON, London; Feb. 4, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Ammonia Saturator.—Ammonium sulphate is prepared by absorbing the ammonia in sulphuric acid flowing over staggered baffle plates in a lead-lined cast iron tower. The flow of gas and acid is counter-current. (1,331,784; ARTHUR ROBERTS of Evanston, Ill., assignor, by mesne assignments, to American Coke & Chemical Co.; Feb. 24, 1920.)

Synthetic Thymol from Para-Cymene.—Para-cymene (1-methyl-4-isopropyl-benzene) is nitrated so that one NO_2 group is introduced in position 2. The nitro-cymene is reduced with iron and hydrochloric acid to amino-cymene or cymidine, which is sulphonated. The cymidine sulphate is converted into cymidine sulphonic acid by a "baking process" similar to that employed for the preparation of sulphanilic acid from aniline sulphate. This produces 1-methyl-2-amino-4-isopropyl-3(or 5)-sulphonic acid. The animo group is eliminated by diazotizing and reducing with alkaline stannous chloride or copper powder and formic acid. The sulphonic group may now be substituted by hydroxyl by fusion with sodium hydroxide. This gives 1-methyl-3-hydroxy-4-isopropyl-benzene or thymol. After acidifying the solution, the thymol is recovered by steam distillation. (1,332,680; MAX PHILLIPS of Evansville, Wis.; filed under the act of March 3, 1883; March 2, 1920.)

Current Events
in the Chemical and Metallurgical Industries

May Meeting of the New York Section, A. C. S.

The regular May meeting of the New York Section of the American Chemical Society was held Friday evening, May 7, in Rumford Hall. Dr. Ralph H. McKee presided. Herbert S. Sidebottom read the minutes of the preceding meeting and then asked Ellwood Hendrick to report on the action of the council at St. Louis. Three papers were then read.

The General Chemistry of Gelatine

Dr. Jacques Loeb, of the Rockefeller Institute for Medical Research, gave some valuable information recently found in his investigations on gelatine. He reported conclusive evidence that the three states of gelatine are entirely dependent on the hydrogen ion concentration.

In using different methods from those generally applied by colloid chemists, the speaker arrived at results which can be summarized as follows:

Gelatine behaves chemically like an amphoteric electrolyte which at hydrogen ion concentrations higher than 2×10^{-5}N combines with anions forming gelatine-acid salts (e.g., gelatine chloride, gelatine sulphate, gelatine ferrocyanide, etc.), and at hydrogen ion concentrations below 2×10^{-5}N combines with cations forming metal gelatinates (e.g., Na gelatinate, Ca gelatinate, etc.). At the hydrogen ion concentration of 2×10^{-5}N (or pH = 4.7)[1]—the so-called isoelectric point of gelatine—gelatine combines practically with neither anion nor cation.

These results can be demonstrated qualitatively in a most striking way. Different samples of 1 g. of finely powdered gelatine are prepared by treatment with different acid or alkali for different hydrogen ion concentrations; the powdered gelatine is then put on a filter, the excess of free acid or alkali is washed off with H_2O, and the gelatine samples are all repeatedly washed in the same way with the same concentration of a solution of salt, e.g., M/64 $AgNO_3$ on the filter (under stirring). The free $AgNO_3$ left between the particles is then washed away with H_2O, the gelatine is melted and so much water is added that the volume is 100 c.c. in each case. The hydrogen ion concentration of each sample is determined. When the test tubes containing these gelatine solutions are exposed to light, those with a hydrogen ion concentration above 2×10^{-5}N (pH = 4.7) all turn brown or black in less than twenty minutes, while the others remain permanently clear. In gelatine solutions with a pH of 4.7 or less, all the silver was washed away; in the solutions above a pH = 4.7 it was not washed away, since it was in chemical combination. In a similar way it can be demonstrated with the proper reagents that in all cases the gelatine samples of a pH > 4.7 contain only the metal of the salt with which the gelatine had been treated, and that all samples with a pH smaller than 4.7 contain only the anion of the electrolyte with which gelatine had been treated, while at pH = 4.7 the gelatine contains neither. This characteristic fact can be demonstrated no matter what the salt is which had been used.

The speaker was able to show that these combinations of gelatine with ions occur in stoichiometrical proportions. Thus Mg, Ca, Ba and SO_4 combine with gelatine in equivalent proportions, while H_2PO_4 combines in molecular proportions.

The speaker has been able to show that these stoichiometrical relations furnish the key for the understanding of the physical properties of gelatine. It was found, for example, that gelatine phosphate shows at the same hydrogen ion concentration almost quantitatively the same osmotic pressure and other properties as gelatine salts with monovalent anion; e.g., gelatine chloride. This was expected from the fact that the anion which combines with gelatine is not the trivalent anion PO_4 but the monovalent anion H_2PO_4. On the other hand, the osmotic pressure, swelling and viscosity of gelatine sulphate are considerably lower, which was to be expected from the fact that the analytical results have shown that the ion combining with gelatine in this case is the divalent anion SO_4. The full experiments were published or will appear in the *Journal of General Physiology* (published by the Rockefeller Institute).

Silica Gel and Its Uses

Dr. W. A. Patrick of Johns Hopkins reviewed briefly his work upon the adsorbent properties of silicic acid gel. This gel is prepared by treating sodium silicate solution with hydrochloric acid. The gel is washed thoroughly and dried at 110 deg. C. in vacuo. Even when dried in this manner, the gel contains 5 to 6 per cent H_2O (as determined by heating in a platinum crucible with a blast lamp), but this is retained so tenaciously that the vapor pressure of water in the gel is zero mm. at 300 deg. C.

With proper precautions this material can be reproduced with definite exactness and this, together with the fact that it is chemically inert, makes it an almost ideal substance for the study of the laws of adsorption. A thorough investigation was made, using sulphur dioxide at various temperatures between—80 deg. C. and +100 deg. C. It was found that the irreversibility of adsorption noticed by previous workers on silica gel was due to the presence of traces of air in the vapor. Experiments with air-free sulphur dioxide showed the process to be perfectly reversible. The empirical equation of Freundich was found to hold over almost the entire range studied. The chief disadvantage in the use of this equation, however, is the fact that the constants are not independent of temperature. Consequently, a large number of isotherms must be determined experimentally.

From a study of their results, Dr. Patrick and his

[1] The symbol pH (Sörensen's logarithmic symbol) represents the logarithm of the hydrogen ion concentration with the sign changed. In the present instance the logarithm of the hydrogen ion concentration is $\log 2 + \log 10^{-5} = 0.30103 + (-5) = -4.7$ or 4.7 with the sign changed, so that pH = 4.7.

co-workers came to the conclusion that the adsorption of gases or vapors at all temperatures below the critical could be predicted from a knowledge of the physical constants of the gas or vapor alone. In developing this theory, a relation between the weight of gas adsorbed and the equilibrium pressure was sought. It was finally found that such a relation did exist if the volume were used instead of the weight and if the equilibrium pressure were replaced by the corresponding condensation pressure, that is $p \div p_o$ where p is the partial pressure of the gas over the adsorbent and p_o is the vapor pressure of the liquid at the temperature of measurement.

But the vapor pressure of a liquid in a capillary tube is lower than the normal vapor pressure because the liquid in capillary is under tension or negative pressure. This effect can be calculated thermodynamically. The corresponding effect on the density of the liquid in the pores can be calculated, provided the compressibility coefficient is known. Unfortunately, this has not been determined for liquid sulphur dioxide, but Richards' relation between surface tension and compressibility ($\beta\sigma^4_3 = k$) suggested the use of σ in modifying the empirical equation.

The following equation (in which the constants are independent of the temperature) was found to hold for the experimental data.

$$V = K\left(\frac{p\sigma}{p_o}\right)^{\frac{1}{n}}$$

For the system silica gel-sulphur dioxide, $K = 0.1038$ and $\frac{1}{n} = 0.447$.

From the industrial point of view, silica gel offers certain advantages as an adsorbent material. While its ability to adsorb gases is about the same as that of charcoal, it is chemically inert and stable up to 700 deg. C. Furthermore, it can be easily and cheaply prepared on a commercial scale. It has been applied industrially in the drying of air and other gases, in the recovery of gasoline from natural gas and also in the recovery of solvents.

Electro-Endosmosis

Dr. T. R. Briggs of Cornell closed the program with an account of electro-endosmosis—the phenomena observed in the transposition of liquids through porous diaphragms when under electric potential. It is a general law that if two substances are brought into contact with each other, the one possessing the higher dielectric constant will become positively charged. Water has a very high dielectric constant and therefore, when under sufficient electric potential and in contact with a stationary diaphragm having a smaller constant, migrates from anode to cathode, conducting electric current in a similar manner to positively charged ions, colloidal particles, etc. If the diaphragm particles were not rigid and were free to move, they would migrate toward the anode, conducting electric current of opposite sign to that carried by the water particles. This latter phenomenon is known as cataphoresis.

Electro-endosmosis has been applied industrially as a means of pumping water from such materials as peat, but the process has not been rewarded with financial success, not, however, because it was an uneconomical or impractical method of drying. Cataphoresis has given a very satisfactory method for preparing pure clay. The clay substance is electrically conducted to and deposited in a revolving drum pole in a very pure state. A series of photographs was shown giving views of a plant and drawings of the installation. In Germany an attempt has been made to generate electric current by pumping water through diaphragms, but the frictional losses were too great to make it a competitor of the dynamo.

New Jersey Chemical Society

The regular meeting of the New Jersey Chemical Society was held in Newark Monday evening, May 10. After an informal dinner President Carleton Ellis opened the meeting. The secretary read the acceptance of many new members and announced that the society now has a membership of 390. Announcement of an excursion to the Seaboard By-Product Coke Co. on Saturday, May 22, was made.

H. E. Otting, assistant superintendent, Nestlé's Food Co., New York City, then gave a résumé of the work done by the chemists in the milk industry.

The Chemist in the Milk Industry

Too much credit cannot be given the chemist to his service both to the manufacturer and consumer of milk. By means of the Reese Gottlieb test he has brought about a standardization of milk and milk products which enables the manufacturer to meet all the existing Government requirements and insures the consumer a standard product.

He has furnished the manufacturer with accurate reports of milk products going into a case of finished goods and so developed plant control work as to keep a close check on all operations, thus reducing costs to a minimum. In addition he protects the manufacturer and consumer by careful inspection of fresh milk received at plant, and tests both raw materials and finished products for conformity to standards.

No minute detail is allowed to escape and special attention is given to the sanitary condition of the plant and its operation so that now the milk industry may be said to be run on a scientific basis.

Various milk products, such as evaporated milk, condensed milk, homogenized milk, malted milk, milk powder and infants' food were exhibited and their process of manufacture described.

Zinc Manufacturing Industry of New Jersey

John S. McKaig, of the New Jersey Zinc Co., gave a brief description of the development of the wonderful zinc deposits of Franklin Furnace, N. J. The concentration of the ores, smelting and refining of the metal, packing and shipping methods were well illustrated with moving pictures of their plant.

Some of the uses of zinc and its compounds, particularly zinc oxide as a pigment in paint and a filler in rubber, were then discussed.

Detroit Engineering Society

The Detroit Engineering Society held its annual meeting in the Palm Room of the Hotel Cadillac, Friday, April 23, with the following speakers: Mortimer E. Cooley, dean of engineering, University of Michigan; William H. Walker, director of the division of industrial co-operation and research, Massachusetts Institute of Technology; Harry M. Nimmo, publisher of the Detroit *Saturday Night;* Frank F. Kedzie, president Michigan Agricultural College, and Gardner S. Williams, of Ann Arbor, Mich.

Fate of Dyestuffs Bill

So successful has been the filibuster in the Senate against the dyestuffs bill that it is practically certain that the measure cannot become a law in its present form. What is more, there seems to be no middle ground on which the contending forces in the Senate can meet. The filibuster was non-partisan. While Senator Thomas of Colorado has taken the most prominent part the movement probably has more sympathy on the Republican side than it has on the Democratic side. The fate of the legislation is very uncertain.

While much of Senator Thomas's four-day speech against the bill was very obviously for time-consuming purposes, a considerable portion of his remarks was especially pertinent. A good idea of his argument, and of the nature of the opposition, however, can be obtained from the following short extracts from his remarks:

"Mr. Irenee du Pont was before the committee, an enthusiastic advocate of this bill. He had a right to come, and it was perfectly proper that he should urge consideration of any measure designed, as this is designed, to encourage his business. The companies which he represents in part are among the most prosperous in the United States. During the war they numbered their profits in hundreds of millions. Taken collectively, I have no doubt that with the exception of the Standard Oil Co. and the United States Steel Corporation, the du Pont aggregation is the most formidable of all American enterprises; and I shall not undertake even to guess at the extent of its accumulated millions. It is in powder, and in all the collateral branches of the industry, and it is also in the dyestuffs business.

"A man representing the colossal combination with untold capital not only demands an absolute embargo, but as high a tariff as possible, so that if the embargo should happen to leak they will still have another wall, amounting virtually to prohibition; and, in addition, he asks for the suspension of the Sherman anti-trust law, not as affecting the entire country but only as affecting the dye industry.

"I do not hesitate to say that if it is necessary in order to sustain this industry that we suspend a law universally applicable and designed to protect the people against combinations, plus an embargo, plus a prohibitory tariff, then we ought not to sustain the industry at all. It is the most monstrous proposition in legislation that has confronted me during my term of service. It is the most impudent proposal that I have encountered while serving upon the Finance Committee. . Its end must needs be absolute monopoly; and I here predict, although I am not a prophet nor the son of a prophet, and may not live to see it, that if this bill becomes a law within the next five years the dye industry of the United States will be entirely in the hands of the du Ponts and the National Aniline Co.

"Embargoes are un-American, to begin with, and even when they are universal they are unjust. During the administration of Mr. Jefferson an embargo was laid upon all foreign commerce. The majority of intelligent sentiment at that time, in my judgment, very properly denounced the policy as a grave and intolerable injustice, but it was at least impartial. Like the dews of heaven, it fell upon the just and unjust. This embargo involves one, and one only, of the industries of the country, and leaves the others to go their way until in good time and due to considerations material, political, and otherwise, the terms of the legislation shall be widened and its wings extended that it may shelter other industries seemingly needing that method of protection.

"I think I have said all that I care to say upon this bill. As I stated some time ago, during the progress of the bill through the Senate I expect to offer two or three amendments, and it is only fair to the Senator having charge of the bill that I should outline them. One is the amendment which I offered yesterday to the anti-dumping bill, and which proposes an income tax upon political contributions in excess of $1,000. Another will be the repeal of the excess-profits tax and the substitution in its place of a consumers' tax. The others will be comparatively unimportant. I shall, of course, when the occasion is appropriate, offer these amendments, and have something to say to the Senate regarding them."

Consideration of Conference Report on Water-power Bill

Consideration of the conference report on the water-power bill was not taken up on May 11, as had been expected. Opposition to the conference bill developed such strength that it was evident that considerable discussion would be indulged in. For that reason the Knox peace resolution was given right of way.

The opposition comes largely from New England Senators, who contend that the bill gives the Federal Government unwarranted jurisdiction over matters coming properly within the province of the state. It is possible that certain changes in verbiage may satisfy the opposition, but as the parliamentary situation makes a filibuster easy of accomplishment it is expected that important concessions will be forced before the Senate is allowed to vote on the conference report.

House Accepts Conference Report

The conference report was accepted in the House by a vote of 259 to 30. On the motion to resubmit the bill to the conference committee, with instructions to insist upon disagreement with the Senate amendments regarding the definition of "navigable waters" and regarding charges, the vote was 86 for recommitment and 209 against. The motion to resubmit also provided for agreeing with the Senate amendment regarding the distribution of power to municipalities, which had been stricken out in conference.

While the adoption of the conference report was hailed on one hand as the best example of constructive legislation of recent years, a very determined minority sees in the bill the surrender of one of the last great public assets and a dangerous infringement upon the rights of the states. The definition of "navigable waters," as agreed upon by the conferees, was declared to violate "settled principles of law" as well as the rights of the states and of individuals. That these arguments did not carry very great influence may be judged from the vote. The vote was not partisan.

Representative MacGregor of New York, one of those voting against the conference report, objected particularly to the amendment requiring a license to distribute power to communities in the vicinity of the plant.

Representative Sinnott, one of the leaders of the House, in the course of his remarks on the bill, said: "All through this bill the right of the state is recognized. The state may fix charges and may also control securities."

Budget Bill

The conferees on the budget bill have practically reached an agreement and promise is held out of legislation before adjournment previous to the national conventions. Budget legislation, which has the approval of both parties, is expected to result in the saving of large sums annually in the conduct of the various Federal agencies. The conference bill will place all responsibility for estimates of expenditures with the President, but will put the Bureau of the Budget in the Treasury Department.

Exports and Re-exports of Chemicals

Exports of chemicals during March, 1920, were valued at $18,885,433, according to figures compiled by the Bureau of Foreign and Domestic Commerce. This is an increase of $5,675,498 in the value of chemical exports for February. Some of the items making up the total, as well as revised figures for March, 1919, are:

Exports of Chemicals:	March, 1919	March, 1920
Acids:	Lb.	Lb.
Carbolic	204,960	214.002
Nitric	58,386	106,883
Picric	633	173
Sulphuric	972,687	2,469,734
Benzol	221.546	221.211
Calcium carbide	2 177 323	3,384,816
Copper sulphate	2,009,234	705.542
Lime:		
Acetate of	174,855	2,807,977
Chloride of (bleaching powder)	1,813,346	2,564,039
Chlorate of potash	69 307	187.152
	Value	Value
Total sodas	$1,492 707	$ 2,525,098
Total chemicals	9 681,692	18,885,433
Total dyes and dyestuffs	880,247	3,635 518
Medicinal and pharmaceutical preparations	1.218.409	1,944,111

Some of the import figures, as compiled by the Bureau of Foreign and Domestic Commerce, are as follows:

		Lb.	Lb.
Acids (except coal-tar acids):			
Oxalic	duty	none	377,523
All other	free	1,750,815	2,011,696
	duty	118,430	515,936
Chemical and medicinal compounds:			
Alkalis, alkaloids and preparations, mixtures of	duty	280.495	670,889
Medicinal preparations	duty	42,055	70,160
		Value	Value
Total coal-tar products		$ 388,399	$ 532,311
Total gums		1,849,377	5,704,581
Total chemicals, drugs, dyes, etc.:			
Free		4.174,504	13,352.532
Duty		3,315,930	7,277,911

Re-exported chemicals, as compiled by the Bureau of Foreign and Domestic Commerce, are:

	March, 1919	March, 1920
Acids:	Lb.	Lb.
Carbolic	1,904	None
Oxalic	None	23,756
All other	7,883	236,111
Extracts and decoctions for tanning:		
Quebracho	36 583	1.170,130
All other	2,341	511,900
Gums:		
Camphor, crude, natural	None	435
Camphor, refined and synthetic	2,350	27,842
Copal, dammar and hauri	315,311	228,989
Gambier, or terra japonica	13,042	4,199
Indigo, natural or synthetic	None	66,109
Iodine, crude or resublimed	1,549	None
Licorice root	2,056	4,902
Opium, containing 9 per cent and over of morphia	1,550	38,744
Carbonate of potash	139,784	1,200
Nitrate of soda	3,083	477
	Value	Value
Total chemicals	$ 566,045	$ 1,200,878

Alcohol as Motor Fuel

Scarcity and high price of petrol have caused the British Government to seek a substitute motor fuel. Among the many possibilities, alcohol from vegetable matter seems most promising. Extensive new laboratories and a special staff of assistants under the direction of Prof. H. B. Dixon are being provided to study this important problem.

Sulphur and Phosphorus Investigation

A second statement of progress has been issued by the Joint Committee on Investigation of Phosphorus and Sulphur in Steel, whose activities have already been mentioned in these columns.*

The committee on statistics has completed a bibliography of the literature. It has also made a survey of used material in the shop of two large Eastern railroads and has secured certain high-phosphorus and high-sulphur material that has been in service, including some connecting rods, a car axle, a crankpin, some parts from a high-sulphur locomotive firebox, and some high-sulphur channels. These will be analyzed and tested by the committee on tests.

A considerable quantity of rivet steel was rolled under observation at the Duquesne works of the Carnegie Steel Co. In all, thirteen ingots (18 x 20 x 72 in. —6,400 lb.) of varying sulphur content, each from a separate heat, were rolled into billets (4 x 4 in. x 4 ft. —220 lb.). In order to eliminate any variable that might be introduced by piping or segregation, it was decided to discard 40 per cent of the steel from the top of each ingot. The next six billets after the top discard, numbered 1 to 6 in sequence, were taken for the purposes of this investigation and each billet was properly stamped with the heat and billet number. Billets 1, 2, 3 and 4 from each ingot were rolled into $\frac{3}{4}$-in. rounds, each billet yielding eight bars 9 ft. 8 in. in length; billets 5 and 6 from each of the ingots were held in reserve. In the attempt to produce a heat high in sulphur, there was obtained the unusually high analysis of 0.17 per cent.

Approximately one-half of the material was shipped to Watertown Arsenal, the U. S. Navy Experiment Station at Annapolis, and the Bureau of Standards, for the various mechanical tests. The remainder was made into rivets at the Pennsylvania Railroad Co. shops at Altoona, and the Champion Rivet Co., Cleveland, Ohio The rivets were made into two types of head, namely, cone and button, and of $2\frac{3}{4}$-in., $3\frac{1}{2}$-in. and 6-in. lengths. Temperature readings of the various bars were taken with an optical pyrometer.

After careful review of all desirable tests and in the light of comments and suggestions, the committee on tests has prepared a schedule covering tension, fatigue, impact, hardness, bend, torsion and shear tests and certain tests for forgeability. Certain "fabrication" tests are also contemplated, which are particularly applicable to the rivet material furnished, such as cold and quench bends, hot flattening, upsetting and tests on the shearing strength of riveted joints.

Proposed Consolidation of Geological Survey and Bureau of Mines

A consolidation of the Geological Survey and the Bureau of Mines is proposed in a bill which has been introduced by Senator Henderson of Nevada, the ranking member of the Committee on Mines and Mining. The consolidated bureaus are to be known as the Division of Mines and Geology and are to be administered directly by an Assistant Secretary of the Interior who "shall be technically qualified by experience and education" for the position.

The bill specifies that the Assistant Secretary in charge of the division is to receive a salary of $10,000.

*CHEM. & MET. ENG., vol. 21, p. 556 (Oct. 29-Nov. 5, 1919); vol. 22, p. 297 (Feb. 18, 1920).

Chem. & Met. to Make Its Own Paper

The McGraw-Hill Co., Inc., together with the United Publishers Corporation, in an effort to solve the shortage in paper, has bought the Newton Falls Paper Mill at Newton Falls, N. Y. This mill, which now manufactures wrapping stock, will turn out magazine stock in the future. Each company holds a half interest in the property, which is valued at approximately $2,500,000.

Philosophical Society of Washington

The May 8 meeting of the Philosophical Society of Washington included a paper by F. B. Silsbee on "Physics of the High-Tension Magneto" and by C. Nusbaum on "The Magnetic Reluctivity Relationship as a Criterion of the Structure of a Eutectoid Carbon Steel." The latter paper is the first of a series of reports which are being prepared as a result of extensive investigations now in progress at the Bureau of Standards studying the correlation of the magnetic properties and physical properties with the composition and prior heat treatment of carbon and special steels.

Personal

Dr. RAYMOND F. BACON, director of the Mellon Institute of Industrial Research of the University of Pittsburgh, who during 1918 was a Colonel in the Chemical Warfare Service, serving as chief of the technical division of the Chemical Warfare Service, A. E. F., has been awarded a citation by General Pershing for exceptionally meritorious and conspicuous services in France.

L. D. BOWMAN, of the Vanadium Alloys Steel Co., delivered a short paper entitled "Some Notes on Annealing" before the regular meeting of the Pittsburgh Chapter of the American Steel Treaters' Society and the Steel Treaters' Research Society on Monday, May 17.

Dr. FREDERIC DANNERTH, who has been retained by the C. Kenyon Co., Brooklyn, N. Y., as consulting chemical engineer, has recently accepted an invitation to become head of the company's new laboratories. He is now planning and organizing the new department and upon completion will assume charge of an extensive program of research and development.

N. E. DORSEY, physicist in charge of the radium and X-ray section of the Bureau of Standards, has submitted his resignation, to take effect at an early date—not later than July 1. Dr. Dorsey has not perfected all of his plans definitely as yet, but he expects to open consulting offices during the latter part of the summer or early fall, specializing in the application of physics to medical practice, particularly X-ray and radium application.

KARL EILERS, recently of the directorate of the American Smelting & Refining Co., has opened private offices at 233 Broadway, New York City.

A. C. FIELDNER, the supervising chemist of the Pittsburgh station of the Bureau of Mines, is conferring with New York and New Jersey state officials in connection with plans for the proposed vehicular tunnel under the Hudson River. He also conferred last week with officials of the Bureau in Washington.

E. D. GORDON, of the weights and measures division of the Bureau of Standards, has resigned to take a position as sales-engineer with the General Automatic Scale Co. of St. Louis. Mr. Gordon will be engaged in both development and special problem work for this company, which contemplates a still further extension of its lines of scales.

N. E. HEHNER, a chemist who has been in the service of the Bureau of Mines, has resigned to enter private employment.

HENRY HOWARD, formerly vice-president of the Merrimac Chemical Co., Boston, Mass., is now associated with the Grasselli Chemical Co. at Cleveland, Ohio.

Dr. C. E. KENNETH MEES, director of the research laboratories of Eastman Kodak Co., landed in England, April 27. While there he will deliver the following lectures before various scientific bodies: "Some Photographic Phenomena in Relation to Astronomy," "Some Results of Recent Investigations on the Theory of Development," "Photography From the Air," "Reaction of the Eye to Light," "A Photographic Research Laboratory," "The Production and Supply of Synthetic Organic Chemicals in the United States," "Rochester and the Kodak Works," "Scientific Research and Industrial Production" and "The Theory of Tone Reproduction With a Graphic Method for the Solution of Problems."

A. G. PETERKIN, formerly assistant general manufacturing manager of the chemical department of The Barrett Co., is now manufacturing manager of the Frankfort plant of the same company.

R. E. H. POMEROY has resigned as smelter superintendent of the Nevada Consolidated Copper Co., and will associate himself with the Bonnot Co., of Canton, Ohio, as chief engineer of its pulverized coal department.

Dr. GEORGE D. VAN EPPS, formerly non-ferrous and oil chemist for the Continental Motors Corp., Muskegon, Mich., is now analytical chemist for the Citro Chemical Co., Maywood, N. J.

C. L. WISWALL, formerly of the Hercules Powder Co., recently accepted a position as production engineer with the Vulcan Detinning Co., Sewaren, N. J.

A. L. WRIGHT, formerly consulting mechanical engineer with the nitrate division of the Ordnance Department, is doing consulting engineering work in Chicago.

E. L. YOUNG has been appointed assistant general manager of the Sunnyside Mining & Milling Co.

Obituary

ARTHUR BENEDICT BELLOWS, first vice-president of the Pittsburgh Testing Laboratory, Pittsburgh, Pa., died Saturday, April 17, 1920.

ARTHUR H. HIORNS, the founder of the Birmingham (England) Metallurgical Society and for forty years head of the metallurgical department of the Birmingham Technical School, died Saturday, April 17, at Water Orton, England.

Prof. A. K. HUNTINGTON, professor of metallurgy at King's College University since 1879, died suddenly on April 17. His appointment terminated in October last year and his colleagues state that his severance from active work had had marked effect upon him. During the war he was engaged in highly specialized work with high explosives for the Admiralty.

JOHN WESLEY HYATT, inventor of the Hyatt roller bearing, died recently of heart disease in his eighty-third year at his residence, Windermere Terrace, Short Hills, N. J. He was born at Starkey, N. Y., and received merely a common school education followed by one year at Eddytown Seminary. Moving to Illinois as a youth, he gave all his time to inventing. Next to the roller-bearing device the most widely known of his inventions is the material called celluloid. His brother, the late I. Smith Hyatt, shared in the discovery of the process of its manufacture. The following list of other patents shows the extraordinary range of his inventive talent: Knife sharpener, new method of making dominoes and checkers, the Hyatt billiard ball (including the machinery for making it), water-purifying

systems, lockstitch sewing machine, machine for squeezing juice from sugar cane, new method of solidifying hard woods for use in bowling balls, golf stick heads and mallets.

Dr. RUDOLPH MESSEL, of London, past-president and for many years foreign secretary of the Society of Chemical Industry, died April 20. His researches with Winkler and others into the manufacture of oleum are classical and were developed commercially under his guidance. Dr. Messel was in his seventy-third year.

Current Market Reports

The Non-Ferrous Metal Market

New York, May 17, 1920.—Conditions are little changed since last week.

	Cents per Lb.
Copper, electrolytic	19.25
Aluminum, 98 to 99 per cent	32@33
Antimony, wholesale lots	10.00
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	55.75
Lead, New York, spot	8.70
Lead, E. St. Louis, spot	8.40
Zinc, spot, New York	8.62½
Zinc, spot, E. St. Louis	7.60

OTHER METALS

Silver	oz.	$99.75
Cadmium	lb.	1.40@1.50
Bismuth (500 lb. lots)	lb.	2.70
Cobalt	lb.	2.70@3.00
Magnesium (f.o.b. Niagara Falls)	lb.	1.60@1.85
Platinum	oz.	110@115
Iridium	oz.	300.00
Palladium	oz.	105@115
Mercury	75 lb.	95.00

FINISHED METAL PRODUCTS	Warehouse Price Cents per Lb.

Zinc, scrap	4.25@ 4.50

The Iron and Steel Market

Pittsburgh, Pa., May 14, 1920.

The rail strike has not extended, in general, rather having waned a trifle, but iron and steel operations, as affected by the rail strike, have not improved during the past week, having if anything grown somewhat poorer. The change arises from the increased scarcity of empties for loading, whether of coal, coke or intermediate or finished products. A great deal of material has been loaded without the cars getting through to destination, and even when deliveries are made the empties have more difficulty in getting back for fresh loadings than the original shipments had in getting through. A trainload of coke, for instance, is made up in the Connellsville region and is "personally conducted" through to a blast furnace, but when the cars are unloaded there are no facilities for taking back the trainload of empties.

STEEL PRODUCTION

The monthly report of the American Iron and Steel Institute, relating to steel ingot production, furnishes a convenient check. The thirty companies contributing to the monthly report produced 2,638,305 gross tons of steel ingots in April, against 3,299,049 tons (revised) in March. These companies made 84.03 per cent of the total steel ingot output in 1918. Allowing for producers not reporting, and counting the number of working days in the month and year, the rates per annum of steel ingot production for the whole industry appear to have been approximately as follows:

	Gross Tons		Gross Tons
January	40,700,000	March	45,200,000
February	44,200,000	April	37,550,000

Thus the rate in April was one-sixth less than the March rate, which was the highest since October, 1918. The month was not equally affected throughout by the rail strike, which began April 1 in Chicago, but hardly affected operations in Cleveland, the valleys and the Pittsburgh district until Monday, April 12, while toward the close of the month operations in the Chicago district had increased. Probably as high an estimate as could be justified for the present rate of production would be the average rate of April.

So much steel has accumulated at mills and in transit that the concern now is not so much about production as about distribution. March production was less than capacity by perhaps 10 or 15 per cent, production is 15 or 20 per cent below the March production, shipments are less than production and receipts by consumers are less than shipments.

A situation is presented that is difficult to analyze. Very little complaint is heard from consumers. The consumers are not exerting any great pressure upon mills to give them preference, and there is even less bidding in the open market for prompt deliveries, at the various premium prices that would be asked, than there was a few weeks ago. Possibly consumers feel it would be futile to attempt to improve their supplies by this means. Possibly many are operating by drawing upon stocks. Possibly it is a common feeling that there is no occasion for haste in making up finished products at the factories.

However the situation is viewed, it is difficult if not impossible to draw any auguries that a stronger steel market is in prospect for the near future. If the operations of consumers are greatly curtailed, then consumption is postponed, and the extra supplies of steel now accumulating, at mill and in transit, will make a larger supply for consumers than has been seen since the steel strike began. If, on the other hand, consumers are operating by drawing upon stocks, then those stocks must have been accumulated at some time, and the only conceivable time for such a process was last February and March, for certainly there were no stocks at the beginning of the year.

As to prospects of consumption, existing capacity is 40 to 50 per cent greater than capacity at the end of 1913, yet in neither of the calendar years 1913 or 1912, though those were the years of largest production before the war, was the actual production within 90 per cent of that capacity, 1912 having had a weak beginning and 1913 a weak ending. For engagement of the present capacity, therefore, a collection of favorable circumstances would appear to be absolutely requisite. The railroads, normally counted upon as large consumers of steel, are buying scarcely anything, and there is merely conjecture as to whether they will become free buyers if or when they receive a favorable settlement of the rate case now inaugurated before the Interstate Commerce Commission. As to large construction jobs, involving the use of steel, hitherto considered essential to there being a full demand for steel, there is not much of that and the immediate prospects are not promising.

BOOKINGS

The United States Steel Corporation reports unfilled obligations at the end of April at 10,359,747 tons. The corporation's rated capacity being about 52,500 tons per working day, the unfilled tonnage would be equal to 7.7 months of operation at capacity, although of course the orders are not uniformly distributed in the different products. The April increase in unfilled obligations was 467,672 tons, against increases of 389,994 tons in March, 216,640 tons in February and 1,020,075 tons in January. April

bookings nevertheless fell short of those in March, since the shipments were less than 96 per cent of capacity in March and 60 per cent of capacity in April. The increase in unfilled obligations in March represented 28 per cent of capacity, the April increase representing 34 per cent of capacity. Adding these increases to the estimated shipments gives 124 per cent as the March bookings and 94 per cent as the April bookings.

When there was such a decrease in the bookings of the low seller, one may infer that there was a larger proportionate decrease in the bookings of the higher sellers, first the group of large independents that have been selling for delivery from two to four months ahead, at, say, $10 to $20 a ton above Steel Corporation or Industrial Board prices, and next the smaller independents that have been selling for delivery in, say, two to six weeks at still greater premiums. Market observation during April agreed with this inference. The independents have not been selling at capacity by any means, and when they have maintained their prices, as the majority have done, it has been at the expense of diminishing order books. Mills that could not permit this, having little tonnage ahead, have had to reduce prices, and thus there have been declines in prices for the earliest deliveries, though the delivery premiums are still large.

Chemical and Allied Industrial Markets

New York, May 14, 1920.

With transportation reported 10 per cent normal, these markets are in such a position that producers have been forced to cut their plant forces in half because of the lack of raw material and fuel, and it is only a question of weeks before they will have to close completely. Jobbers and brokers are in a bad way, as the only supplies within easy access of New York are the unimportant items for which there is small demand. One large drug house in Boston is operating a fleet of 5-ton trucks between that city and New Jersey, but the cost of transportation of this kind is figured on 1c. per lb. gross weight, which would make the cost prohibitive for general use.

General Chemicals

Glauber's salt went up 10c. per cwt. during the week, with still further tightening of supplies. This item was listed at $1.20@$1.35 a year ago, and current quotations range from $1.75@$2.05 per cwt. One factor in this item is reported thirty cars behind his contract and is refusing to consider any new business. Producers have firmly set the price on *carbon bisulphide* at 8@11c. per lb., with fairly good supply on hand at these figures. *Caustic soda* is still nominally quoted around $6.50 per cwt. for spot material; offers have been received from Japan below the present market for resale American material, but so far none of this material has arrived. All items on the *acid* list are decidedly firm; demand for *acetic* is still heavy, with 28 per cent listed at $3.50@$3.75 for car load and $3.80@$4.00 for less than carload, while glacial 99½ per cent holds firm at $16.50@$17.50 per cwt. *Hydrofluoric acid*, 52 per cent, continues in good demand at the recently fixed price of 12@14c. per lb., while *hydrochloric*, 20 deg., is still nominal at $3@$4 per cwt.

Coal-Tar Products

No improvement has been noted in this market during the week. Conditions as previously reported still prevail and there is very little material being offered on any of the items throughout the list. *Naphtha* has shown some indications of weakening, and it is said some material changed hands at 14c., but 15c. of last week still holds as an average price. *Alpha naphthylanine* came up during the period and is listed at 65@70c. per lb., against 50@60c. of the previous report. There is very little of this material being offered even at the new price. *Benzol*, water white, can be had for 27@36c. and 90 per cent is 25@31c. per gal. f.o.b. plant. *Toluol*, in practically the same position, suffering from shipping conditions, is listed at 28@32c. per gal. subject to delivery.

Naval Stores—Flotation Oils

Quotations on these items remain wholly nominal and the listed price will take effect upon arrival of material from the primary market. *Turpentine* came down slightly and is now quoted at $2.45 per gal., against $2.50 of last week. All grades of *rosin* have changed hands at prices ranging from $19 to $24 per 280 lb., but these prices will be broken shortly, as the Savannah market has already shown some signs of weakness. Practically the same thing holds true of the flotation oils, as material en route from the South is being held up, which upon arrival will relieve the present pressure.

Vegetable Oils

Dullness has been the predominating note of this market during the week. Buyers are not displaying any interest in future offerings due to the uncertainty of the transportation tangle. Business has been done in a small way on some of the items, but that is the best that can be said. *Linseed* is handicapped by the delivery problem. There has been increased activity on this item recently, but producers in the West are unable to ship any goods. Current quotations are firmly maintained at $1.72 per gal., raw, car lots; $1.67, raw, tank cars, and $1.75, boiled, car lots, with contracts subject to delivery.

Miscellaneous Materials

Like all other markets, there is very little material moving into this market. *Feldspar* remains unchanged with $13.50@$18, ground grade, f.o.b. New York State, still holding firm, while *barytes*, listed at $36@$40 for white floated, is in a wholly nominal position. *Fullers earth* is still scarce and $25@$30 for domestic and $35@$40 per ton for foreign is firmly maintained.

St. Louis, May 11, 1920.

The local production of heavy chemicals is curtailed due to manufacturers' inability to get raw material and supplies regularly on account of the railroad switchmen's strike. Railroad service is from 15 to 30 per cent normal. This situation has materially affected the chemical market and supply of practically all chemicals is very limited. No relief is expected until railroad service is back to normal. Prices are erratic and are based on supply available. The St. Louis district has had to depend almost entirely on local manufacturers to supply their needs.

Sulphuric Acid—Supply is practically limited to local production and stocks are low. The 60 deg. grade is quoted at $15 per ton and 66 deg. grade at $22 per ton. Oleum is quoted at $27 per ton.

Muriatic Acid—The demand exceeds the supply and quoted at $20@$22 per ton for the 18 deg. grade. The muriatic acid plant of the Monsanto Chemical Works, East St. Louis, was partially damaged by an explosion in a nearby oil refinery and production is temporarily curtailed.

Sodium Bisulphate—Supply limited and quoted at $4 per cwt.

Nitric Acid—Local supply practically exhausted and demands exceed local production.

Zinc Chloride—Available supply exhausted. Last quotations approximately $4.50 per cwt.

Zinc Oxide—Demand for this chemical is heavy and local output for second quarter practically all contracted for. Last quotation 9½@10c.

Phenol—There is a good demand for phenol, which is quoted at 12c. per lb. Supply is plentiful due to surplus which the Government is disposing of.

Caustic Soda—Supply is very limited, although several shipments have been received lately. It is quoted at 7c. per lb. 76 per cent test in carload lots.

Soda Ash and Silicate of Soda—Local supplies practically exhausted.

Hydrofluoric Acid—Local supplies practically exhausted.

Chicago, May 13, 1920.

Existing conditions in regard to transportation are such as to cause reports on Chicago market conditions in the chemical trade to be of almost purely local interest. While it is perhaps true that in general the railroad situation is

improving and that shipments are moving a little more freely now than two or three weeks ago, the chemical market has experienced but little relief. A great portion of the traffic in chemicals takes fifth or sixth class in freight classification and therefore receives but scant consideration in the present emergency. The effect has been practically to isolate Chicago from the rest of the country and to put each purchase purely on a basis of how much the buyer can afford to pay rather than go without the needed goods.

Stocks in most lines are probably lower than they have ever been before. It is now possible to procure shipments in limited extent from manufacturing points to Chicago and from Chicago to most destinations. Direct shipments from points outside of Chicago, through Chicago to a third city as the point of destination, are still impossible. This works as a severe handicap on direct shipments.

The tendency of buyers to stay out of the market unless their needs are absolutely essential to the conduct of their business, which was noted two weeks ago, continues. The consuming trade recognizes the fact that present conditions are such as to make it purely a sellers' market, and they are therefore reluctant to enter the buying field. This tendency has prevented any general skyrocketing of prices, though in practically all cases spot market is considerably above the figure asked for goods on contract for future delivery. Collections are, of course, tight. The greatly lengthened period of time consumed by goods in transit has tended to make payments slow all along the line and is amounting to a severe burden on both the dealer and the manufacturer.

The shortage of spot stock is most severely felt in the coal-tar products and in the alkalis.

Heavy Chemicals

Previously noted conditions tending to keep the prices of various grades of *alcohol* at a very high level have become accentuated by the difficulty of manufacturers securing raw materials, particularly molasses. The current market quotation on *ethyl* grade of $5@$5.50 per gal. is purely nominal. Actual transactions of the past two weeks have been very small in quantity and have ranged in price all the way from $6 to $10 per gal. *Methyl* grade is just about as scarce as ethyl, and while the ruling quotation is about $3 per gal. for 190 proof, spot goods are moving at a considerably higher figure. *Denatured*, not so scarce as the others, is quoted slightly higher than in the past, $1.05 being today's quotation. *Formaldehyde* is in no better supply, and the price remains constant at about 65c. per lb. Manufacturers are pretty well sold up on future production capacity and are becoming reluctant to make new contracts.

A more insistent demand is felt for alkali products than for any other line. Raw materials are hard to get, containers are scarce, and the goods themselves are hard to move after production and packing is completed. *Bleaching powder* continues to rise in price, with present quotation 4@5c. per lb., f.o.b. cars at factory. *Soda ash* is in very light supply and most manufacturers report their product sold up for the remainder of the year. Nominal quotation remains at 4½c. per lb., with spots bringing as high as 5c. This week's transactions in *caustic soda* have ranged from 6¼c. to 7c. per lb., and contracts for future business are being placed at 7c. per lb. in cars f.o.b. works. Conditions on *salsoda* are unchanged, ruling price being $1.35 per cwt. f.o.b. factory and $1.60 per cwt. out of Chicago stock.

The *glycerine* market continues very strong, quotation on c.p. grade being 26c. per lb. Purchases of this commodity in the past few weeks have been so heavy as apparently to assure a figure at least this high for some time to come. *Aqua ammonia*, reported last week as selling at 10c. out of stock, has lately been run up as high as 11c. This is wholly on account of the difficulty of obtaining material, as manufacturers are still quoting 8¼@8½c. per lb. on contracts. The last quotation of 16c. per lb. for white granulated *salammoniac* holds good, but deliveries at that or any other figure are hard to get. Demand is very light, consumers recognizing the difficulty of procuring shipment. Liquid *chlorine* remains very firm and manufacturers show no anxiety to close contracts at the prevailing figure of 8@8½c. per lb. *Sodium nitrite* seems to be in better supply, with the price unchanged at 26c. per lb. Actual transactions in all of these commodities are very light.

The scant movement of acids, particularly *sulphuric*, is causing stagnation in many lines of the chemical industry. Prices show much more strength than they have for some time past, but the market has not been stampeded by the present conditions which are recognized to be only temporary. *Sulphuric* acid, 66 deg., is quoted for early delivery at $24 per ton and for immediate delivery, that is, as soon as shipment is possible, at $25 per ton. Increases in the price of raw material have affected *acetic* acid, increasing the current quotation on 28 per cent to $3.75 per cwt., and on 56 per cent to $8.40 @ $8.50 per cwt. Almost no actual transactions are taking place in *muriatic* acid, on which quotation is 34c. per lb. for 22 deg. *Nitric* has recovered from past depression and is now quoted at 7½c. per lb. for 42 deg., and *oxalic*, with almost no supply visible, is tightly held at 56c. per lb.

Coal-Tar Products

The coal-tar product market seems to be the most seriously affected of all chemical lines by the present strike situation. Recovery had not been complete from the derangement occasioned by the coal and steel strikes when the present trouble started, and the situation today seems more serious, so far as production is concerned, than ever before. Supplies of crudes are on a hand-to-mouth basis and prices at which goods are actually changing hands vary widely. *Benzol* is bringing about 30c. per gal. for spots with no change recorded on prices of contract orders. Makers have practically no supply of *solvent naphtha* on hand and what few current transactions are being recorded are at about 32c. Small supplies of *naphthaline* are available, current prices being, for balls 18c. per lb.; flakes, 17c. per lb. *Toluol* is also difficult to get and current price ranges from 29c. to 31c. per gal. No price changes of moment are recorded in coal-tar acids, the quotation on *benzoic* being 75c. per gal. for technical and 90c. per gal. for c.p. *Salicylic* is quoted at 50c. per gal. for technical, and 55c. per gal for c.p. The supply of intermediates is so short as to render any quotations impossible. *Aniline oil* and *aniline salts* both remain in heavy demand, with prices ranging from 40c. upward on the oil and from 50c. upward on the salts.

Vegetable Oils

The condition noted last week of no supplies and likewise no buyers continues in effect. Local price on *linseed oil* in barrels remains unchanged at $2.05 per gal., but the carload price has fallen off somewhat. This quotation ranges from $1.65 to $1.70 per gal. Demand is very light.

Prices are weak on all the other oils. *Soya bean* is quoted in sellers' tanks, f.o.b. Coast, at 13½c. per gal. and in barrels, f.o.b. Chicago, at 18½c. Crude *cottonseed oil* under light demand is a shade off to 16c. Prime summer yellow remains firm at 18c. and refined deodorized in barrels still brings 22½c. *Cocoanut oil* is down a little to a present quotation in sellers' tanks, f.o.b. Coast, of about 16½c. No market seems to exist on corn oil, the nominal quotation for prime grade in tanks being 15¼ @ 16c. per lb.

Flotation Oils—Naval Stores

Present price on turpentine should probably be about $2.30 per gal. To this, on local sales, is being added the cost of trucking from various railroad points from ten to thirty miles from Chicago. This has caused the current figure for turpentine in barrels to be placed at $2.56 per gal. Reacting to a feeling that the transportation difficulties were going to be shortlived, on May 3 the price was dropped from the previous quotation of $2.57 per gal. to $2.25 per gal. The resulting renewal of buying and the prolongation of the rail trouble forced the price back to the present figure in one week. *Pine oil* remains high, *.933 pure steam distilled* now standing at $1.80 per gal. and *pure destructively distilled* at $1.70 per gal., these prices being for barrels. *Pine-tar oil* holds the previously quoted price of 42c. To a great extent these prices are nominal, there being practically no supply.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0.65 – $0.75
Acetone	lb.	$0.19 – $0.20	.21 – .22
Acid, acetic, 28 per cent	cwt.	3.50 – 3.75	4.00 – 4.25
Acetic, 56 per cent	cwt.	6.50 – 7.00	8.75 – 9.00
Acetic, glacial, 99½ per cent., carboy	cwt.	15.50 – 16.00	16.50 – 17.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities

Alpha naphthol, crude	lb.	$1.05 –	$1.15
Alpha naphthol, refined	lb.	1.40 –	1.60
Alpha naphthylamine	lb.	.65 –	.70
Aniline oil, drums extra	lb.	.34 –	.45
Aniline salts	lb.	.46 –	.50
Anthracine, 80% in drums (100 lb.)	lb.	.90 –	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 –	2.10
Benzidine, base	lb.	1.35 –	1.40
Benzidine, sulphate	lb.	1.20 –	1.25
Benzoic acid, U. S. P.	lb.	.90 –	1.00
Benzoate of soda, U. S. P.	lb.	.80 –	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 –	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 –	.31
Benzyl chloride, 95-97%, refined	lb.	.35 –	.40
Benzyl chloride, tech.	lb.	.25 –	.35
Beta naphthol benzoate (nominal)	lb.	.50 –	.65
Beta naphthol, sublimed (nominal)	lb.	.70 –	.90
Beta naphthol, tech (nominal)	lb.	.45 –	.55
Beta naphthylamine, sublimed	lb.	2.25 –	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 –	.19
Ortho-cresol, in drums (100 lb.)	lb.	.23 –	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.10 –	1.20
Cresylic acid, 95-97%, dark, in drums	gal.	1.00 –	1.05
Cresylic acid, 50%, first quality, drums	gal.	.65 –	.75
Dichlorbenzol	lb.	.08 –	.10
Diethylaniline	lb.	1.40 –	1.50
Dimethylaniline (nominal)	lb.	—	1.80
Dinitrobenzol	lb.	.30 –	.37
Dinitroclorbenzol	lb.	.30 –	.35
Dinitronaphthaline	lb.	.45 –	.55
Dinitrophenol	lb.	.40 –	.45
Dinitrotoluol	lb.	.40 –	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 –	.40
Diphenylamine (nominal)	lb.	.55 –	.65
H-acid (nominal)	lb.	2.25 –	2.50
Metaphenylenediamine	lb.	1.15 –	1.80
Monochlorbenzol	lb.	.12 –	.15
Monoethylaniline	lb.	1.70 –	1.85
Naphthaline crushed, in bbls. (250 lb.)	lb.	.15 –	—
Naphthaline, flake	lb.	.15 –	.17
Naphthaline, balls	lb.	.16 –	.18
Naphthionic acid, crude	lb.	.75 –	.85
Nitrobenzol	lb.	.14 –	.17
Nitronaphthaline	lb.	.40 –	.50
Nitrotoluol	lb.	.20 –	.30
Ortho-amidophenol	lb.	3.25 –	4.25
Orthodichlorbenzol	lb.	.15 –	.20
Orthonitrophenol	lb.	.80 –	1.25
Ortho-nitro-toluol	lb.	.35 –	.40
Ortho-toluidine	lb.	.35 –	.40
Para-amidophenol, base	lb.	2.50 –	2.50
Para-amidophenol, HCl	lb.	2.90 –	3.25
Paradichlorbenzol	lb.	.08 –	.12

Ohio

ASHLAND—The Alboy Co. will soon award the contract for the construction of a 2-story, 200x200-ft. factory for metal stamping. Estimated cost, $150,000. Dercum & Beer, 4500 Euclid Ave., Cleveland, archts.

CLEVELAND—The Holan Mfg. Co., 3809 Clark Ave., has awarded the contract for the construction of a 1-story, 43x164-ft. drying kiln and a 44x150-ft. mill at 5809 Parkbrook Rd., to F. J. Jirka, 4216 Warren St. Estimated cost, $100,000.

DELAWARE—The Delaware Water Co. plans to build a 2-story filter plant.

WOOSTER—The Akron Brass Mfg. Co. has awarded the contract for the construction of a 1-story, 50x185-ft. foundry and machine shop, to J. S. Smythe, Wooster. Estimated cost, $26,000.

Pennsylvania

PHILADELPHIA — The Atlantic Refining Co., 1211 Chestnut St., plans to construct an oil manufacturing plant addition on Snyder Ave., west of 29th St.

WASHINGTON—The Hazel Atlas Glass Co. is building a 1- and 2-story, 100x368-ft. glass factory at its plant here. Estimated cost. $500,000.

Rhode Island

CENTRAL FALLS (Pawtucket P. O.)— The United Nets Corp., 229 4th Ave., New York City, has awarded the contract for the construction of a dyehouse and bleachery on High St., to the Central Const. Co., Pawtucket. Estimated cost, $20,000. Noted May 4.

South Carolina

BENNETTSVILLE—The Mailboro Fertilizer Co. plans to build an 80x200-ft. fertilizer factory.

CAYCE—The Seminole Fertilizer & Oil Co., Jacksonville, Fla., plans to build a fertilizer plant.

CHESTER—The Baldwin Cotton Mills has awarded the contract for the construction of a sewage disposal plant to Tucker & Horton, Charlotte, N. C.

Virginia

RICHMOND—The Standard Paper Mfg. Co., Hull and Canal Sts., is building a factory for the manufacture of blotting paper. Estimated cost, $150,000. J. H. Wallace & Co., 5 Beekman St., New York City, archt. and engr.

Wisconsin

HORICON—The Columbus Canning Co., c/o C. L. Davidson, supt., has awarded the contract for the construction of a 2-story, 96x108-ft. canning factory on Main St., to F. J. Pluckhahn, Juneau. Estimated cost, $40,000.

MILWAUKEE—H. A. Poppert Mfg. Co., 505 Cedar St., has awarded the contract for the construction of a 26x52-ft. foundry on 5th St., to Byrne Bros., 2112 Burleigh St. Foundry equipment will be installed in same. Estimated cost, $5,000.

TOMAHAWK — The Pride Pulp and Paper Co. plans to build a paper mill. C. B. Pride, pres.

Wyoming

LARAMIE — The Standard Oil Co., Casper, is building a Burton Process pressure plant here. The plant will consist of principally ten 8x40-ft. pressure stills and necessary storage equipment and will handle distillates for the Midwest Refining Co.

Quebec

MONTREAL — The Congoleum Co. of Canada has awarded the contract for the construction of a 70x118-ft. building on St. Patricks St., to the Atlas Constr. Co., 37 Belmont St. Estimated cost, $105,000.

Ontario

PETERBORO—The city plans to build a sewage disposal station and pumping plant. Estimated cost, $50,000. R. H. Parsons, City Hall, engr.

PORT CREDIT—The village plans to construct a waterworks system. Plans include a chlorination system and the installation of mechanical filters, etc. Estimated cost, $80,000. E. A. James Co., Ltd., 36 Toronto St., Toronto, engr.

LONDON—The W. T. Rawleigh Co., 55-65 Liberty St., Freeport, Ill., will receive bids about June 1 for the construction of factory buildings for the manufacture of pure food products on Adelaide St. Estimated cost, $300,000.

NEWMARKET—The city will soon award the contract for the construction of a sewer and activated sludge plant. Estimated cost, $65,000. E. A. James Co., Ltd., Toronto St., Toronto, engrs. Noted Jan. 7.

SUDBURY—The High School Bd. will soon award the contract for the construction of a 3-story school. Chemical and physical laboratory equipment will be installed in same. Estimated cost, $200,000. P. J. O'Gorman, archt. Noted March 17.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold a regular meeting June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its twelfth semi-annual meeting as follows: June 28 and 29 will be spent in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY OF REFRIGERATING ENGINEERS will meet in St. Louis May 27 to 29.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA plans to hold its annual convention in the Auditorium Theater, Chicago, Ill., May 19, 20 and 21.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NEW JERSEY CHEMICAL SOCIETY will hold a regular meeting and ladies' day Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J.

THE SOCIETY OF CHEMICAL INDUSTRY, American Section, will hold a meeting, May 21, at the Chemists' Club.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

Industrial Notes

THE WILSON-MAEULEN CO., New York City, has appointed Harry Goldsen, a practical instrument man, who knows the company's electrical pyrometers thoroughly, both from the manufacturing and service sides, as its new representative in the Pittsburgh district. He will have charge of both sales and service in that territory.

THE CELITE PRODUCTS CO., New York City, announces the appointment of Lyle Stockton Abbott as head of the Eastern sales department. Mr. Abbott succeeds H. A. Mannshardt, resigned.

THE FOUNDATION CO., New York City, announces that Edwin J. Beugler has become associated with it as vice-president in charge of engineering. Announcement is also made of the appointment of Joseph H. O'Brien as chief engineer.

THE HARRISON SAFETY BOILER WORKS, which has been carried on for many years as a co-partnership by Joseph S. Lovering Wharton, William S. Hollowell and John C. Jones, has been incorporated under the laws of Pennsylvania, charter perpetual, as the H. S. B. W.-Cochrane Corp. with the following officers and board of directors: Joseph S. Lovering Wharton, president; John C. Jones, vice-president and general manager; William S. Hollowell, secretary and treasurer; Horace E. Sibson, general sales manager, and Alexander B. Wallen, general works manager. The corporation takes over, as of date Jan. 2, 1920, the entire business of the former firm, acquiring its assets and assuming its liabilities.

YORK, REGAN & BURKE has been organized as a partnership with headquarters at 1323 North Clark St., Chicago, Ill., for the purpose of general consulting work as architect and engineer, embracing concrete engineering, buildings, bridges, concrete steel structures, industrial plants and other civil engineering work.

THE ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, makes several announcements: First, the following new orders for Greaves-Etchells electric furnaces: Wayne Steel & Iron Co., Croghan, N. Y., 1-ton furnace; Stora Kopparbergs Bergslags Aktiebolaget, Domnarfvet, Sweden, one 20-ton for steel ingots; Soc. Métallurgique de la Loire, St. Etienne, France, two 10-ton for steel ingots; S. A. C. Electriques de Charleroi, Belgium, one ½-ton for castings; Carlisle Steel Co., Sheffield, one ½-ton for tool steel; Sproat Marley & Co., Newcastle, England, one 1-ton for steel castings. Second, the successful starting up of the Greaves-Etchells electric furnaces at the following companies: Dodge Steel Castings Co., Philadelphia; American Radiator Co., Buffalo, N. Y.; Hammond Steel Co., Syracuse, N. Y.; Charles Bertolus, Bellegarde, France; Fonderie Ambrogie Necchi, Milan, Italy. Third, the following appointments of agents and representatives for the Greaves-Etchells electric furnaces: H. M. Smith, 39 Schofield Bldg., Cleveland, Ohio; A. S. Lindstrom, 519 California St., San Francisco, Cal.; McCrum & Gillem, 1011 Empire Bldg., Birmingham, Ala.; D. P. Morisseau, General Welding & Supply Co., Wainwright Bldg., St. Louis, Mo.

Manufacturers' Catalogs

WILLIAM R. PERRIN & Co., Chicago, Ill., is issuing a new filter press circular.

LEEDS & NORTHRUP Co., Philadelphia, Pa., calls attention to a pamphlet, Catalog No. 90, entitled "The Hump Method for the Heat Treatment of Steel," which describes a radically new way of hardening steel. Accurate measurement of temperatures and the independent determination of transformation points are rendered unnecessary. The work is heated in an electric furnace in contact with, or near to, a thermocouple. A recording instrument draws upon a large scale chart a curve of the electromotive force developed by the thermocouple. While the work is passing through the transformation or decalescence point, the rise in temperature is arrested, producing a decided jog or "hump" in the line. The operator allows the work to remain in the furnace a definite number of minutes after this hump appears and then quenches. The results claimed are entire uniformity of heat treatment, including grain size, hardness and tensile strength, together with freedom from distortion, breakage, decarbonization and scale. In addition, there are certain advantages due to the use of electric furnaces, such as cleanliness, low upkeep charges, ability to locate the heat treating department in the machine shop where the material can be treated in the direct course of manufacture, thus reducing handling charges and bringing all operations under the supervision of one man. A number of large concerns are using this method for hardening tools and dies and for the quantity production of automobile gears, races for ball bearings, etc. The total cost of operation, including labor and electric current is said to be less than that of fuel-fired furnaces, where quantity rates for current can be obtained, while the quality of the product is improved and standardized.

Congress and the Air Nitrate Projects

THE special House Committee of War-Time Expenditures on Air Nitrate Projects by the Government has made its majority and minority reports, as recounted at considerable length on our news pages. This conforms to Congressional tradition, which is the same as that of country lawyers. The Speaker appointed a majority of his own party and a minority of the opposition to the committee, and its members straightway established themselves as attorneys for their respective parties. The people were hardly represented.

The principal recommendation of the majority related to the big Muscle Shoals works and proposed that it be leased and converted into a fertilizer plant for the sale of products direct to farmers with the right of the Government to take it over in time of threatened war.

This is a recommendation in regard to the general welfare. It might very probably be the report that any majority would have made, whether it consisted of Republican or Democratic conservative politicians who shy at anything that smacks of Government control of a specialized industry. But immediately a minority member registered a protest against the report, not on the ground that another alternative was better, but on the ground that it was an invasion of the function of another committee of the House. This was twaddle and it was overruled, but whether it was overruled because it was twaddle or because it was registered by a Democrat, while the Speaker is a Republican, is a secret that will probably always remain hidden in the Speaker's breast—and it is doubtful if he could reveal the truth about it if he tried.

Then the majority condemned the Government's entire war-time program and charged reckless waste and extravagance. They say the blame rests on President WILSON and BERNARD M. BARUCH, Mr. BARUCH being the moving spirit of the war-time project. The assertion, however, has no significance whatever, because, if Mr. WILSON had been a Republican, the same majority would have praised him for doing exactly what he did and admired Mr. BARUCH even beyond his real deserts. And the Democratic minority would have found no merit in it. As it was they found no fault. The majority vote of censure is not a register of opinion; it is merely a register of political tropism.

Then, to put the Administration into a hole, the majority proposed that no further sums be paid to the Air Nitrates Corporation, on the ground that it failed to perform its contract; the institution of civil suits was recommended for recovery of damages, and it was urged that the whole question of pay (i.e., the payment of debts incurred by the Government) be "threshed out" in the Court of Claims. Threshed out is the right expression. The chance of collecting a debt against the Government in the Court of Claims with governmental counter-suits pending is a weary process. If the liquidation can be completed within twenty years it will be speedy work. Members of the majority may strut and shout until they are blue in the face about their integrity of purpose, but they cannot prevent it from appearing that they were willing to cause the Government to default in its obligations rather than miss the chance to embarrass the opposition. There was no effort to serve the people by either side that a careful reader can discover. They did what they had to do to avoid blame for themselves, and devoted the major portion of their efforts to get their opponents into trouble. The whole thing is sickening.

Suppose a commission of engineers were selected to build a smelter, not because of their merit as engineers but to provide a body of men unevenly divided between persons with red hair and those with black. Suppose whatever men of one complexion did the others declared to be wrong and that the whole caboodle of them were more interested in fixing blame on the opposition than in getting the smelter built. What kind of a smelter would result? Then suppose after it was built its operations were carried on by just this sort of "party government." When would dividends begin?

Here we are with the threat of madness over civilization confronting a great part of the world, and the trouble is contagious. And we have not enough strong men of character in Congress to shame their fellows into a sense of their obligations to the people. Nobody wants to know how incompetent the other side is. Everybody knows both sides are incompetent. There is no use in telling us so any more. We do not want the choice of the lesser evil. What we want is the greater good, and vituperation will not bring it to light. What a pity that the men we have elected to represent us cannot understand this!

National Organization Of Engineering Societies

DOUBTLESS all national, regional and local engineering societies have some time since received proper notification from the Joint Conference Committee of the Civil, Mining, Mechanical and Electrical Engineers of the organization meeting to be held at Washington, D. C., on June 3. Therefore it is unnecessary to dwell upon the importance of this item of news, but it is well for engineers in general to think carefully upon the issues which impel the present movement toward a national organization.

It may be said that the Joint Conference Committee is an outcome of a slow accumulation of sentiment in the ranks of the American Society of Civil Engineers,

which after years of growth took visible form in the appointment of a numerous committee on development, to consider ways and means whereby the individual engineer could get more direct advantage in a human rather than a technical way from his engineering society. Other engineering societies took similar action for a variety of reasons which would be tedious to relate, but in all of these committees there was a well-expressed idea that some inclusive organization would be necessary to express properly the engineers' desire for service and influence on such public affairs as they are qualified to speak of with authority, and to consider the welfare of the profession of engineering in its broad general aspects.

Hence the Joint Conference Committee, delegated from committees on development from the four national societies, met and formulated a plan of organization which was duly reported back to the parent institutions. These societies, by appropriate action, approved the plan in principle, and appointed delegates to the forthcoming conference, apparently, however, without power to bind their parent societies to such action as may be taken at Washington.

In fact, the development activities within the Civil Engineers were responsible for a very recent letter ballot, wherein the membership by decisive majorities called for such action as would increase the engineer's influence in public affairs, yet by a small majority rejected the plan advised by the Joint Conference Committee. Briefly, this proposed organization is not intended to be (in the words of one of its sponsors) "a super-society of engineers. It will have no membership of individuals, but will be composed entirely of delegates representing organizations already in existence. In its object it does not encroach on the province of any engineering organization at present in existence."

This last statement may fairly be questioned, as well as doubt expressed as to whether the method of representation will appeal to all engineers any more favorably than it did to the Civils. It may be pointed out that the new organization is not a society, but a federation. The ultimate member will be well represented only in case his particular society is peculiarly responsive to his needs. If memory serves correctly, not so long ago an appeal to American engineers for funds for Engineering Council (in itself an organization having no membership of individuals, but composed entirely of delegates) met with extremely meager response. On the other hand, during the last year the American Association of Engineers increased its membership from 4,000 to 17,000, and received $170,000 for investment in active work of the organization, which indeed seems to include the avowed purposes of both the poverty-stricken Engineering Council and the proposed new federation.

Unquestionably the spirit of unrest is stirring engineers as well as it is any other group of individuals in the present-day world. It is calling for engineering societies which shall justify their existence by service to the individual rather than for their officials. Engineers are worthy of a more influential voice in our public activities, and some organization will spring up to satisfy this demand. But in view of the history of Engineering Council, the Civil Engineers' letter-ballot, and the phenomenal growth of the A.A.E., it can be plainly concluded that the successful society will not be composed of delegates, but rather of individuals.

Inquisitive Ignorance In the Foundry

OF COURSE we younger metallurgists had an inkling of it in our own minds, without immodest self-confidence. Yet it sounded good to hear the gray-headed expert ("expert" is the proper term), the seasoned consultant with his kindly eyes, repeat in all seriousness, "The educated young man now in the foundry is its salvation."

The hearer was feeling pessimistic that morning, and mentioned the fact that perhaps twenty-five years ago there was a great furore to put a chemist into the foundry. No foundry was complete without either a rack of test tubes or a file of analysis reports. Yet even today relatively few of the foundries which delude themselves with "chemical control" really appreciate what "chemical control" means. If the analyses are not laid away to rest alongside innumerable of their brothers on file, no serious effort is made by the melter to see that the charges are actually and carefully weighed. So why should the few technical men going into the foundries be so important?

"I'll grant you that the foundry is full of rule-of-thumb methods, and has a strong tendency to revert to type," said the older man. "When I first worked in a locomotive shop I well remember no one could cast engine cylinders but the HARE boys. If they were both sick, well, there were no cylinders made until they returned. They had their favorite cheeks, and their own peculiar sand. All the molders knew these, but did not know the feel of the sand when it was properly mixed, they would ram it just a bit too hard, or the gaggers would not be bent at the exact crook, or the cope would not be vented just so nor would the HARE boys ever tell just how they determined when the iron was exactly right. They were acknowledged the best molders on engine cylinders, and they intended to remain so.

"That works still remains, and the HARE boys are no longer molding cylinders, yet better engines than ever are turned out every month, and at a tremendous rate, despite the old-timers!

"About ten years ago the management decided to rebuild the rambling assemblage of miscellaneous shops into one consistent manufacturing establishment capable of turning out their steadily increasing business. They employed some real engineers, who studied the requirements of that particular concern, and in the end provided a modern plant containing all the mechanical features the heart could desire. The foundry was an inspiration!

"Naturally, but unfortunately, BILL RIDDLE, who had been foreman of the old foundry for thirty years, was continued in charge of the new plant. The bigger job was too much for him, and in order to be on the safe side, he saw to it that the workmen made car wheels exactly the same in 1910 as they were made in 1885. Of course, expected output did not materialize, nor could anyone tell RIDDLE anything or help him. The way he had done since youth was safe and good enough, and he was going to run the whole plant himself, since he was in charge!

"Finally the manager asked me if I could suggest a way out of their trouble, and I told them that they should select three or four of their best and keenest young men, and impose them upon BILL as assistants. Of course BILL would make a terrible fuss, and lead the

boys a dog's life for a while, but he must be given to understand that all were to work together rather than pull apart.

"In a year or so BILL RIDDLE retired, it is said with dire predictions of the fell consequences. Yet the best of the boys is now superintendent, and the plant is steadily improving and exceeding the designer's predictions. So you can see I have at least one good reason for my abiding and instinctive faith in the genius and capacity of the inquisitive young men coming into the foundry, who do not know so much about the correct way to do things that they are not afraid to put some of their foolish inspirations to trial!"

Inefficient Distribution of Labor

THERE is a "shortage of labor" in the United States. One may say that is a curious if not impossible situation, for if everybody is working and everybody is consuming it cannot make a great deal of difference how many there are all told, whether 50,000,000 or 100,000,000. If there is a shortage of workers why not an equal shortage of consumers, and there you are! It was a different thing at various times in the past when the entire population were consumers or would-be consumers, but through some mischance all could not get jobs, hence could not get the wherewithal to purchase things for consumption.

Large corporations are usually efficiently managed these days, but a large corporation is not well managed merely through having the proper total number of employees. It is in a bad way if it does not have a capable president, and the president's office is in a bad way if it does not have a proper supply of capable office boys. Each job must be properly filled, and the efficiency is not what it should be if there are men who are doing work that is beneath their ability. Everyone should have the opportunity to do the best work he is capable of doing.

The United States is not thus aligned as to its working forces. There is a very inefficient distribution of labor, using the term "labor" in its broadest sense. Thousands of school teachers have resigned from positions where they were very useful, in order to take positions as stenographers and clerks. Janitors and street sweepers get pay far in excess of the proportions formerly obtaining. Men able to do better things are engaged at common labor, but as they don't like that kind of work the common labor has been going to higher and higher premiums. Railroad work has been disorganized by workmen receiving higher pay than the foremen who direct their work.

The way we have been muddling along is that if there is not enough common labor we pay a disproportionately high price for common labor, and if there is still not enough, the more skilled crafts reduce their performance to strike a balance.

When immigration has been shut off for years it is natural that there should be a shortage of common labor, and as each finished product, whether a dwelling house, a skycraper, a steel rail or a bushel of potatoes, requires its certain percentage of unskilled labor and of skilled labor there is a deficiency in production. If skilled workers were working as well as formerly, there would not be enough work for them to do, on account of the lack of the proper proportion of common labor, but they endeavor to bridge the gap by doing less in a day. This may seem well enough to them, although the high cost of living is making some of them think, but in any event it is not efficient. Should competition among skilled workers arise, as there has been competition in the past, it would be found that not enough work could be given them, by reason of the scarcity of men to do the common labor.

The scarcity of common labor is due, of course, to the failure of immigration, and immigration needs to be stimulated, whereas the literacy test, enacted by Congress at the behest of organized labor after successive Presidential vetoes, is one thing that curtails immigration. The country is suffering from lack of common labor, and skilled labor is suffering. Some time it may suffer still more. The question is whether it realizes, or can be brought to realize, its mistake, in opposing immigration. If we had no plumbers and found it much more costly to train plumbers than to allow plumbers from abroad to come into the country, it would certainly be advantageous to bring them in.

It used to be complained that the foreign-born workmen saved up their money and sent it abroad to friends and relatives, or even carried it out of the country with them. We were under the painful necessity of exporting goods to equalize this and other portions of the "unseen balance of trade." Nowadays we bribe men to do common laboring work by paying them high wages and instead of saving their money they buy silk shirts, hence the high cost of living. The silk shirts do not do them any particular good and the man who feels he is really entitled to wear silk shirts is disgruntled.

"Technically and Commercially Successful"

AN ANNOUNCEMENT of a co-operative agreement which has been perfected by the Bureau of Mines with certain individuals for the study of lignite coking and briquetting has been made public. The agreement puts special emphasis upon the desire that there be established "a technically and commercially successful business." Both parties are to be congratulated that there is such definite recognition of two essential elements in any investigational plan.

There is a great deal needed to be known about lignite and its properties, about the products, solid, liquid and gaseous, which result from its carbonization, and about the possibilities of briquetting lignite and lignite chars. It is to be hoped that many of these uncertainties will be cleared up and valuable information afforded our engineering talent for future development of this important fuel resource that today lies practically unexplored and untried.

However, the business side of any such process is just as important to the engineer as the science and technology, and it is very satisfying therefore to find that the two elements so important in the development of this new industry are placed upon a par in the program of work announced. One cannot expect that both elements will be wholly illuminated by such a limited expenditure as the $300,000 which will be invested under this co-operative agreement. However, the very limited knowledge now available in this field should be greatly extended, and the possibility of further future development made much more promising.

Readers' Views and Comments

Engineering Conference on Public Service

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 910 of your May 12 issue you entirely misinterpret the Notice to Engineering Societies. The Organizing Conference, meeting in Washington, June 3 and 4, is not a meeting of the Joint Conference Committee, but is a meeting of representatives of all national and local engineering and technical societies to organize the representative national body which shall embody the "public service" element of all American engineers. The Joint Conference Committee was authorized by the four large engineering societies to issue this call for a conference to organize this body along the lines of the Joint Conference Committee's report to the four large engineering societies.

JOSEPH W. RICHARDS,
Acting Secretary, Joint Conference Committee.

Bethlehem, Pa.

To the Engineers of America

To the Editor of Chemical & Metallurgical Engineering

SIR:—None of the undersigned has been active in "politics" heretofore; nor are we now! But we believe that our country needs just one kind of a man to guide its fortunes during the next four years.

He should be a man understanding the underlying causes of the present nation-wide unrest—the economic as well as the social causes; a man who has administered large affairs successfully, handled vast sums economically and honestly; has employed laborers with sympathy and success; one having executive experience; who has made his way up from humble beginnings and therefore understands the psychology of the man who works with his hands; one who has the courage to combat squarely, whether in the board-rooms of corporations or in the councils of ignorant or vicious "Soviets."

We need a man not only "favoring" economy in the National Administration, but an avowed advocate thereof, with the knowledge gained from experience of how a budget system is prepared and also how it should *work*; in other words, a sane and tried "efficiency expert."

America needs a man who has seen and knows actual conditions overseas and who can guide our international relations with firmness and sympathy, justice and honor; a man who has met face to face and understands those who lead the councils and influence the policies of European nations, new and old; who has had not only the grace to say "Yes," but the courage to say "No!" when necessary, not only to our late enemies, but to some others abroad who would take advantage of American sympathy or generosity—yes, and to some of the few here who would "profiteer."

Some of us know and respect one or more of the men who are seeking in an honorable way to secure the Presidential nomination, and others who are also favorably thought of; *but has anyone of them the first-hand knowledge of our national and international problems that are in the undisputed possession of Herbert Hoover?* We think not!

We believe it is possible that he can be nominated, even without a political machine behind him; that the American people can constitute themselves a "Committee of the Whole" whose choice will be triumphant, *provided the "vox populi" can be made audible!*

How can this be done? By bringing it about that the people shall not only speak out what we believe is in their hearts but that their voice shall be *heard.*

We are members of one or another of the great Engineering Societies of America, but we have neither asked nor do we expect these organizations to act as *such.* But if each engineer, before whom this letter appears, will constitute himself a committee of one, each in his own locality, to spread the well-known facts of Herbert Hoover's career, personality and attainments and *to bring to the delegates of his own state the knowledge of his neighbors' demand* that Hoover shall be the nominee, this result will surely be attained. No one knows better than the political leaders of all parties that if nominated *he is sure to be elected.*

Will the American engineers help to bring this about?

For further information write to the Engineers' Hoover Committee, 480 Lexington Ave., New York.

An Accounting Mystery

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the issue of April 21 you express regret that the House and Senate had declined to grant a fund to the Bureau of Standards for the preparation and distribution of standard samples. Later, you say that the work was really self-supporting. If it was self-supporting, why is a fund necessary for its continuance? Why can the Bureau not continue to distribute samples and show a profit from it? If it was not self-supporting, why continue to state that it was?

A. A. N.

It is no wonder that A. A. N. is somewhat mystified at the Government accounting system which does not permit a self-supporting fund to be such in effect as well as in name.

With reference to the standard sample fund of the Bureau of Standards, the fund requested is $5,000. The fees last year were $6,000 in cash and $4,000 or more additional in credits for work done for state and Federal departments that do not pay cash. These funds, however, are not available to the Bureau of Standards but go into the Treasury, to the credit of the United States. Therefore, it makes no difference how much money the Bureau takes in in fees, it has absolutely none of it to spend for continuing the work. As a consequence, it might be more nearly correct to say that the work was self-supporting as far as the Government was concerned, but as far as the Bureau of Standards is involved any expenditures it makes cannot be recovered from income, no matter what the fee may be in size or character. [EDITOR.]

Corrosive Action of Soils on Iron and Lead

An Outline of Field and Laboratory Tests on Electrolysis of Metal Parts Buried in Many Soils, Together With a Brief Summary of the Experimental Results and Derived Conclusions

By L. A. STENGER

ONE of the features of industrial conditions little noticed by the average person is the multiplicity of pipe lines, cables, conduits and various other metallic structures found in the subsoils of cities. These structures, with the exception of earthenware sewers and conduits and bituminized fiber conduits, are constructed from cast or wrought iron, steel and lead. The iron and lead are used for water pipes, iron is used for electrical conduits and gas pipes, and lead, usually containing 2 per cent of tin, is used as a protective covering for electric power and telephone cables. Rails of street railways may be included with these structures, also steel foundations of buildings and steel tunnel linings.

Usually these pipes, etc., are placed in the soil with the idea that they will not be affected, at least to the point of destruction, by any corrosive agencies. Attempts are sometimes made to paint or coat the metallic surfaces for protection, more often not.

An enormous amount of work has been done investigating the causes of corrosion of iron and lead in air and the methods for their adequate protection. Comparatively little has been done investigating and preventing corrosion of these metals in soils.

There have been several theories advanced to explain the corrosion of iron. These are the electrolytic, the carbon dioxide or acid, the hydrogen peroxide, the oxidation and the biological or bacterial. From the results of work on this subject, together with a study of the publications of Whitney, Cushman, Gardner, Walker and many others on corrosion in general, the present author believes that practically all corrosion, of both iron and lead, is electrolytic in action.

Corrosive Action of Soil

The general study of the subject was begun with field observations of underground structures in different places. Extensive work of this type was done at Havana, Cuba, in 1911, by S. T. Todd, of the General Electric Co., and the writer. At that time a new sewer system was being installed, the excavations for which offered a rare opportunity for observing the many piping systems buried in the ground. There it was found the corrosive action of the soil on iron was severe. The most damage was done to the smaller iron gas and water service pipes. From reliable information from several sources, it was found their life was from three to seven years, for either wrought iron or steel pipes. A poorly galvanized pipe would corrode as badly as a black pipe. A good heavy galvanized coat was an effective protection. Corrosive action was very marked also on cast iron pipe. Careful work was done to find leakage electric currents where this corrosion occurred. None was found. The street railway rails carry practically no current, the double trolley system being in use. The rails of two electric lines entering the city carried current; these were the only sources of leakage current in the city, and, owing to the good soil conductivity, damage from that current would be localized closely to the lower potential points of the tracks. No damage had been reported from this cause. Furthermore, corrosion had been common in that city before electricity had been used at all, therefore it is absolutely certain the pipes were corroded by reactions between soil constituents and the metal.

In Indiana there was laid in 1891 an 8-in. steel gas pipe with screwed wrought iron couplings. This pipe extended from the Grant County gas fields to Crawfordsville, where it ended about one-half mile from an electric railway. This pipe was taken up in 1911. It was corroded in local areas over the pipe, at many places through the walls, and generally over the whole length of the line. It was buried 3 to 5 ft. deep, lying in moist yellow clay soil. This corrosion was also due to reactions between soil constituents and iron.

In Pierre, S. D., cast iron water pipes have been replaced on account of damage due to soil corrosion only. Small iron service pipes were corroded to leakage in six years. The subsoil there is a heavy clay

Cast iron and steel pipes have been found in Minneapolis and St. Paul, corroded to destruction in black peat soil, cinder fills and clay. These soils were found to be actively corrosive.

Commercial lead is very long lived under ordinary circumstances. However, in Havana it was found that lead covers of some insulated electric cables laid in earthenware conduits were destroyed in three years. This occurred where silt had leaked into the conduits, and where, at times, water ran through them. The lead water service pipes buried in clay were in an excellent state of preservation, and all observations and information indicated that they were undamaged.

Corrosion Is Electrolytic or Auto-Electrolytic

Consideration of these facts and others leads to the classification of corrosive effects into two types. One, called electrolysis, is the resultant of an outside generated electrical current flowing from the metal by an electrolytic conduction path. The other has been termed auto-electrolysis; it is electrochemical in nature, and nearly all corrosive effects on subsoil structures, not caused from electrolysis, are produced by it. These two types are to be clearly differentiated, although it has been found that their effects are similar, and as they are so nearly related, any study of corrosion should include consideration of each, especially when corrosion causes are under investigation.

Localized corrosive action on iron, commonly called pitting, may easily destroy gas or water pipes, as a leak is caused in a comparatively short time. The

electrolytic theory may be applied to explain such corrosion. Iron has a high solution tension, which causes iron ions to leave its surface under electrolytic conditions, as in moist soils. This ionic travel sets up an electric current. If there is a particle of material electronegative to iron and in contact with it, the current will be directed and will flow from the iron through the adjacent soil to the electronegative area back to the iron. The result will be iron going into solution and becoming oxidized to hydrated iron rust, which is insoluble, porous and an electric conductor. The hydrogen formed by this electrolysis is oxidized to water. If free hydrogen were formed, as in rapid action, the current would be reduced or stopped by insulation due to the gas film on the electronegative area; that is, the miniature battery would be polarized. But it is found by experiment that all the hydrogen is oxidized, and no gas is evolved, and that the action is continuous until the iron is all removed in the immediate vicinity and a pit results. This action is then auto-electrolysis. Any bare iron structure in soil is subject to auto-electrolysis, as the soil will always be more or less an electrolyte, as it contains soluble salts, or acid ions, and moisture.

On account of the number of variable factors found affecting corrosion rates, it becomes rather difficult to isolate and to study them effectively. Considering the metal alone, prominent factors affecting its corrosion rates are constitution, properties of components, segregations, foreign substances including gases, states of strain, solution tension and conditions of surface.

External factors involving the soils and conditions outside of and in contact with the metal are moisture content, gases, composition, electrical conductivity and components. The latter may be chemically corrosive, electronegative to the metal and catalytic in action. Also porosity or density, homogeneity, concentrations, bacterial conditions, temperature and pressure are to be included.

Potential Explorations

At the beginning of some laboratory work done by the writer under direction of Prof. E. E. Nicholson at the University of Minnesota, some experiments were carried out, electrolyzing cast iron and sheet steel in solutions. They show that the iron goes into solution at a rate of 1.042 g. per amp.-hr., approximately. This is with a valence of two. Further work was then done using several irons in different soils, to compare all effects under the various conditions, and to find the corrosion rates both by electrolysis and auto-electrolysis. For electrolysis in soils many tests were run, using different soils and iron, steel and lead anodes. Tests were made on iron anodes with scaled, smooth, or polished surfaces. Various voltages and current strengths were used. After deducting for the corrosion due to auto-electrolysis as determined under the same conditions without any applied electric current, the efficiency of electrolysis was determined. From all results, about two-thirds of the iron anodes having an electrolysis corrosion efficiency under 100 per cent gave an average of 81 per cent efficiency. The remaining 33 per cent of anodes at 100 per cent efficiency and over gave an average of 110 per cent. Lead anodes gave an efficiency of from 80 to 150 per cent. From these results no law connecting any of the variable factors with a definite electrolysis efficiency was noted.

Electrical or galvanic phenomena found in connection with auto-electrolysis were studied. Two identical electrodes of copper (platinum could have also been used) were made, and covered with pads of cotton cloth or filter paper. These terminals were connected to a suitable electrometer. Wetting the pads with dilute acid and placing them on an iron surface, an electromotive force was produced. The resulting current was caused by the iron ions passing into solution at a faster rate in one electrolyte than in the other. The effect is also observed after using soil under the terminals instead of pure acid electrolyte. The energy generated is dependent on various factors, and the voltage is due primarily to the solution tension of the metal.

Current Strength Studied

Studies were made of these potentials and the resulting current strengths. A Weston 15-volt voltmeter is a suitable instrument to use for measurement of voltage with electrodes as described about 1 in. in diameter. This instrument does not indicate the full voltage generated, on account of the limited current flow. A special inclined capillary Lippman electrometer was constructed for this work and found excellent. It takes no current and indicates potential up to 0.8 volt accurately. A Weston milliammeter may be used to measure the current. In making such electrical surveys on bright pure iron, usually the electrode put down first is found to be electropositive. The current flow would be from the iron under it. Using ordinary moist clay as electrolyte and two similar copper terminals, placing one clay first on pure bright iron, and in a few seconds the other in another place on the same piece of iron, closing the circuit with the copper terminals through the Lippman electrometer, voltage up to 0.1 was indicated. The copper terminals may be reversed, also reversing the electrometer, to determine if there is any voltage due to dissimilarity between them—there should be none. Care should be used to avoid contact between terminals and iron.

With this method, using moist soils as electrolytes, potentials were measured between points on many kinds and conditions of irons found in commercial use. On clean ordinary surfaces would be found 0 to 0.1 volt, clean iron to mill scale 0.3 to 0.5, clean iron to copper 0.8 to 1.0, clean iron to carbon 0.8 to 1.0, clean iron to red rust 0.3 volt. The clean iron would be electropositive in all cases; current would leave it and cause corrosion.

Causes of Auto-Electrolysis

The destructive effects of auto-electrolysis depend upon the electronegative material to a considerable degree. If it is a copper coating with a flaw exposing iron, then under auto-electrolytic conditions a hole will be corroded through the iron in a surprisingly short time. A superficial corrosion will expose the graphitic carbon in cast iron; an area is thus electronegative and the iron ions are removed through the porous electrolyte-saturated soft material, characteristic of corroded cast iron. Mill scale, if thick and unbroken, is a good protection to iron, but if broken becomes a source of danger, since it is electronegative. In soils where the electrolytic conditions are not favorable for corrosion, as in clean sand, action may be suspended indefinitely, only a small amount of rust forming.

Corrosion of Purest Ingot Iron

Pitting will occur in polished, pure irons (analysis 1) in a clean well-mixed clay, due to the same causes

with no apparent electronegative areas on the iron itself to direct or localize the reaction. This may be due to either or both the following causes: slight differences in the iron itself, or concentration cells set up in the clay. Using the Lippman electrometer with electrodes of similar metal, preferably small platinum wires, surveys over a piece of moist clay showed potentials of 0.01 to 0.02 volt between different points. Attempts were made in this way to locate the low potential points on a smooth clay surface. Then a polished, pure iron plate was placed on it. Allowing action to continue a few days, the iron was examined to see if the corroded areas had any definite relation to these low points. Fair correspondence was obtained on one specimen, but others did not give definite results. These potentials are very difficult to locate, but it is probable they aid in starting local actions on the iron surface, producing red rust in small amount. This is electronegative, and action then becomes definite, and pitting proceeds.

A special corrosion cell was used to duplicate conditions of underground structures for further experiments on auto-electrolysis measurements. Three-inch bituminized fiber conduit was cut in sections about 3 in. long and filled with soil, in which was placed the iron plate. Sheet rubber disks placed in the ends made them air- and moisture-tight, and paraffined wooden disks over these completed the cell. With this arrangement, the specimen could be subjected to pressure. Sets were made up to determine the effects of different pressures and temperatures encountered in practice.

Corrosion of Lead

Lead, having a very low solution tension, is not so susceptible to auto-electrolysis as is iron. External conditions will produce corrosion, however, in a somewhat different manner. If two soils are in contact with a metal, one of which contains a substance subject to a change of valence, we may expect an electrical current flow. This current will enter the metal as part of its circuit, and leave it again, in the near proximity of the bi-electrolytic soil, causing corrosion of the cathode areas. Examples of lead corrosion of this type are given in a paper by E. H. Schofield, Minneapolis, Minn., and the writer, *Electric Railway Journal*, 1914, p. 1092.

7. No. 20 sheet.

Lead is also liable to corrosion from other conditions. Pipes leaving moist cement floors often corrode near the floor line. Cable covers lying in cement ducts and lead pipes in mortar walls are also destroyed. If water from condensation or other sources is allowed to collect or run down or around a lead structure under conditions when soluble salts are present, there will be formed a concentration cell. The electromotive force set up is caused by different velocities of different ions, which would be found in any surroundings of a pipe in cement or soil. The more dilute solution would be the fresh moisture supply; the more concentrated solution would be near the metal surface in the surrounding medium. Common specific instances of this type of corrosive action are seen at the bases of iron poles at the ground line. It occurs also if the pole is set in cement. This is a plausible explanation of the corrosion of the lead cable covers at Havana, previously mentioned. The bottom side of the cover lay in silt, electrolytically more concentrated. The dilute solution would be from condensation and the water flowing intermittently in the conduit, in contact with the upper surface of the lead.

The complete report of this investigation necessarily

carries much detail which need not be included in this review. Tests on approximately 150 soil samples collected in the different cities mentioned, and the fact that many types of iron and lead specimens were treated in these soils, will give an idea of the scope of the work. Some representative results are given in Tables I and II. The influence of the moisture content of clays is shown in the chart, but this also shows that the electrolytic nature is variable in the different clays. Analyses of several soils were made, and it was found that the combined sulphates and chlorides had the greater influence in increasing corrosion. Although the amounts of these components are small in an average soil, and perhaps not over 0.5 per cent in the most active clays, yet their action is remittent and continuous, and corrosion proceeds without renewing the supply of acid ions.

An engineering crime often committed is that of placing iron pipes in cinders. Cinders have carbon particles, sulphates, and carry much moisture. This furnishes a most excellent example for illustration of the electrolytic theory of corrosion, as there is at once formed numerous localized electric batteries, where the iron is the positive and corroded element, carbon the electronegative pole, and the sulphates dissociate and form a very active electrolyte. As a result, the iron pipe is certain to leak, sometimes within a year.

Conclusions

Some other conclusions derived from these experiments may be stated as follows:

Electrolysis of underground structures may be caused

by certain definite conditions, which may be determined by electrical measurements and a study of the environments.

The electrolytic theory is applicable to corrosion of underground iron and lead structures.

In comparing the corrosive resistance of different types of irons and steels, a careful study should be made of the conditions under which the metals are to be used, and tests conducted under these conditions. Conclusions should not be based on a few experiments, but many tests should be conducted and studied. A good factor for comparison is the "corrosion rate per unit area corroded per year." This factor varies with different metals and with different external conditions, as shown in Table II. Iron specimens should be treated at least 400 hours or longer if possible. The moisture content of the soils in the cell should be maintained constant. The corroded areas usually are definite on the cleaned test plate and may be measured by planimeter.

From experiments performed, and corrosion rates found, the probable life of an iron structure in given soils may be predetermined. The weight of $\frac{1}{8}$-in. iron 1 sq.in. in area is 15.8 g. Assuming corrosion forms

The 4-in. cast iron pipe, 41.5 in. long, was treated 0.85 year. Cells in glass beakers. Large pipe in wooden cell. Loss by water evaporation determined by weighing cells at intervals and replaced by adding pure water.

a conical pit, the metal removed weighs 5.2 g. Referring to Table III, the scaled mild steel specimen in clay showed a yearly corrosion rate per square inch of corroded area of 0.51 g. As $\frac{5.2}{0.51}$ is 10.0 years, this is the probable life of a mild steel black iron pipe with $\frac{1}{8}$-in. wall, buried in an average moist clay soil.

The ordinary coatings, mill scale, poor grades of galvanizing, casting skin and tar dips on cast iron have little value as protection against auto-electrolysis, and in cases accelerate it. Tar dips lengthen the life of cast iron by delaying the action, but the coating will soon fail in spots.

The longer life of cast iron is due to its greater wall thickness.

Corrosion rates of iron are little affected by temperature changes within the range usually found about water pipes.

Corrosion rates are appreciably increased by pressures within the range of pressures met in practice due to depths of burial.

TABLE III. AUTO-ELECTROLYSIS IN DIFFERENT SOILS

Clay A, St. Paul	0.0198
Dark gray clay, Pierre, South Dakota	0.0613
Yellow clay, Indiana	0.0915
Light gray clay, Havana, Cuba	0.0295
Yellow clay, Havana, Cuba	0.3240
Blue clay, Minneapolis	0.0597
Peat D, St. Paul	0.2300

Ingot iron, analysis 1, 1.3x2.5-in. polished plates. Grams iron lost after treating 528 hours in fiber cells. Water content approximately the natural percentage.

Admitting or excluding air from a test cell has no appreciable effect on corrosion rates.

The life of underground iron structures could be greatly prolonged by placing a few inches of sand around them, especially in clay, cinders and moist electrolytically active soils.

Denver, Col.

Industrial Courts in Great Britain

In response to questions asked in Parliament on March 3, 1920, Sir Robert Horne, British Minister of Labor, stated that the Industrial Court established by the industrial courts act, which received the royal assent on Nov. 20, 1919, had been duly set up. The president of the court is Sir William MacKenzie, Violet Markham and Cecile Matheson representing the women.

The court is a standing arbitration tribunal, the provision of which was one of the recommendations of the Committee on Relations between Employers and Employees, better known as the Whitley Committee. It is the desire of the government that trade disputes should be settled as far as possible by negotiation between employers' associations and trade unions. In cases where agreement is impossible recourse can be had to the Industrial Court, provided consent of both parties to the dispute is forthcoming. One of the advantages of reference to a standing court is that the experience of the members of the court in dealing with difficulties in other trades is placed at the disposal of the parties to a particular dispute.

The Minister of Labor went on to say that since Nov. 20, 1919, 208 differences have been referred to the court. These have been heard mostly in London, but the court has also sat in Glasgow, Dublin, Belfast, Liverpool, Manchester, Sheffield, and elsewhere in its ordinary form, by which three members of the court—a chairman, a representative of the employers, and a representative of the employees—constitute the court, while a certain number of cases have been dealt with in different parts of the country by single members of the court. The differences have chiefly concerned questions of wages, but many other industrial matters have come before the court. The court has settled the general wage arrangements for the Scottish building trade, gas undertakings throughout Great Britain, the spelter trade, the clay industry, the bobbin and shuttle making industry, the seed-crushing and oil-milling industry, and the organ-building trade, and wages of women employed in railway shops.

The court has at present before it claims for national increases of wages in the engineering, shipbuilding, and explosives trades, together with the wages of railway shopmen. "As far as I am in a position to judge," Sir Robert concluded, "the court appears to have commended itself to both employers and employees. It is recognized to be an impartial and independent tribunal, and I think that it will continue to serve a most useful purpose in the national life."

A Comparative Test Upon High-Speed Steels—IV

Chemical Composition, Microstructure, and Manufacturing Methods Which Distinguish the Really Superior Brands—It Is Perfectly Feasible for the Metallurgist in the Smaller Shops to Determine the Tool Best Suited for His Requirements*

By A. J. Langhammer, M.E.†

After the test had been completed and the winners decided upon, there was still one point to be determined of fascinating interest from an industrial engineering standpoint.

Why did steels with an almost ideal chemical composition and good microstructure fail utterly? It was believed that an inspection tour of the various plants making tool steel would possibly shed some light on the matter. Happily, the writer was able to take this trip, and though it was impossible to visit all of the mills whose product was tested, due to limited time, yet a representative group was inspected. The principal points investigated were the organization, shop and laboratory equipment, personnel, plant laycut, manufacturing methods, inspection methods and the raw materials used.

Good High-Speed Steel Is Strictly a Quality Product

Coming into the steel plants in this manner with a fresh viewpoint and having access to all departments, it was relatively easy to detect deficiencies or, better still, to ascertain why some brands simply *had to be* of superior quality. A well-balanced organization, modern, high-grade equipment, properly planned and executed work, experienced and careful workmen, together with the best only of raw materials and expert supervision, cannot help but be reflected in the product. Then, too, there are elements of refinement (analogous in a way to that of polishing and buffing the domes of cylinder heads on a very high-grade motor) that some steel manufacturers do not incorporate in their product. As a matter of fact, whenever the policy was such that everything was sacrificed for quality and no product except such as met the established standard was shipped, an excellent steel was produced.

The above-stated general conditions are, of course, essential in the manufacture of a good steel. It is felt, however, that there are some additional important factors that will bear special mention, and for this reason they are listed below.

Raw Materials

A good iron as basic material is invaluable. Especially is this apparent where the refinement of the iron is controlled by the tool steel mill. The same is of course true of the other alloys, though in this case there are relatively few mills that control the production of the bulk of their raw metal. This latter feature is very desirable, especially when a market scarcity exists in the rarer elements. The chemical composition of the iron, both before and after refinement, should be held to close limits and frequent examinations made for the presence of slag and other inclusions.

Melting

Furnace construction and condition, grade of crucibles, correct mixture and temperature control are vital factors in melting practice. In pouring, the best practice is to eliminate the ladle and pour the ingot direct from individual crucibles. Each ingot, then, after annealing, should be analyzed and graded. If a steel mill makes various grades, it thereby effects quite a saving in costs over the "one-grade mill." Rigid inspection for surface defects should follow naturally.

Forging

Uniformly slow pre-heating and accurate temperature control for the forging operation are essential. Hammers of sufficient size or capacity should be used and in the same way the ingot must be of large enough cross-section to permit a sufficient reduction in area. When an ingot is worked in the rolling mills, the various factors must be controlled and a high standard set. Subsequent chipping or grinding is then followed by another inspection.

Miscellaneous

In the mixing of the alloy, especially where the electric furnace is used, there is an excellent opportunity for the introduction of "elixirs" (if that term may be used) such as uranium, and quite a bit of work is being done to this end. An advantage that few modern high-speed steels possess in any marked degree is that of being able to withstand the high heat in hardening without scaling. Needless to say, this is of prime importance in the manufacture of taps, hobs, form tools, etc., especially where the hardening is done in an open fire and not by packing.

Discussion of Results

Perhaps the most interesting data of the whole test are those presented on the two graph sheets, Figs. 5 and 6, reproduced herewith. Quite a few factors are brought out clearly, two of which appear of extreme importance, and which should be classed as essential requisites when a test of this nature is planned. They are the *number of specimen tools* used per braid and the *time limit on which failure should occur*. By an inspection of the graphs, it is at once obvious that no two tools of any one brand (of the same bar, heat treatment and subjected to identical working conditions) gave the same results. In most cases a wide variation is found, indicating that at least four and possibly six tools must be used if the results of a test are to be reliable. It is

*For Parts I, II and III, see Chem. & Met. Eng., vol. 22, Nos. 18, 19 and 20, May 5, 12 and 19, pp. 829, 889, and 939.

†Industrial engineer, Thompson & Black, engineers and accountants, New York and Detroit.
Formerly mechanical engineer, Packard Motor Car Co.

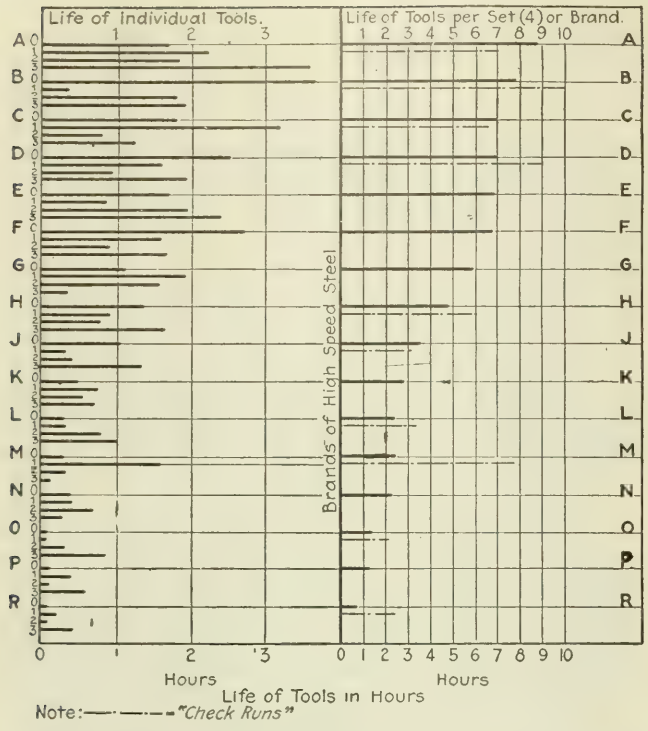

FIG. 5. CURVE SHEET OF FIRST RUN

Turning Liberty motor cylinders 5½ in. diameter. Tool with $\frac{1}{16}$-in. radius nose; cutting speed, 35 ft.; feed, 0.054 in.; depth, $\frac{5}{32}$ in.

felt that this is a point of great importance, because conclusions are often based on the performance of one tool only and the above results indicate that such a test really means very little. When but one tool is used, the results may flatter a brand or do it great injustice with equal equanimity and in either case the consumer is the loser. The steel company, too, in such an instance does not have the proper opportunity to show the quality of its product.

The other point of importance brought out in the graphs is that apparently when a tool is not forced or put to heavy duty, a mediocre steel may show up almost as well as a good brand. As the average plant probably does not exact a high duty from the high-speed tools in use, this fact explains why an inferior or even a poor brand may give fairly satisfactory results. Attention is invited to the fact that a superior steel will demonstrate its worth regardless of the duty exacted. For example, see steel B and D in both graphs. In the first run it will be remembered the cutting speed was 35 ft., the depth of cut $\frac{5}{32}$ in. and the feed 0.054 in., while in the second run the other factors remained the same except that the feed was increased to 0.090 in. A steel which is less excellent but still may be classed as "good" does not always fare so well, as is shown, for instance, by brand K. At this point it will probably be well to consider the exactly opposite performance of brand A, which finished as the leader in the first run, and in only the sixth position in the second run.

In the heat-treatment chart it will be noticed that this steel was treated with cyanide while at the high heat, the resulting "case" probably aiding the steel materially in the first run. After failing while cutting and then being reground (the case being removed in grinding) the beneficial effect of the case hardening was removed and the steel was graded as "good" steel only and not as a "superior" brand. While it appears that the cyanide treatment possibly aids a tool to some extent, its application should not be encouraged because it provides for non-uniformity, causes gasification and gives off dense, obnoxious fumes at the high heat, and distracts the attention of the tool hardener to a most undesirable extent. It is also to be noticed, from an examination of Table IV, page 941, that the nose of tool number 1 of brand B broke during the first run, thereby preventing this brand from finishing as the leader in this run also, to which position it unquestionably is entitled.

Check Runs

Attention is directed to the "check runs" indicated on both graphs. These additional runs were conducted to check the results of the leaders primarily, but as long as a check run was being made it was decided to include some of the other brands where the possibility of accidental performance such as broken tools indicated that they might be entitled to a higher standing. Steels of exceptionally promising analysis were also included in the check run. On every case a different bar of steel was procured from a standard supply; tools were then made up and put through the test like the first batch. It is to be noticed that the sequence as established by the original runs was not altered except in the case of brand M, which steel moved up to third position. This was to be expected because experience with brands C and J, previously occupying that position in the first and second runs respectively, had indicated that both steels were very non-uniform. Besides, they gave a lot of trouble in hardening. The rest of the check runs resulted in relatively unimportant changes in standing except that in nearly every case the "life" was greater than that of the original results. This fact seemed to indicate that brands D and B would at least duplicate the performance exhibited during the test

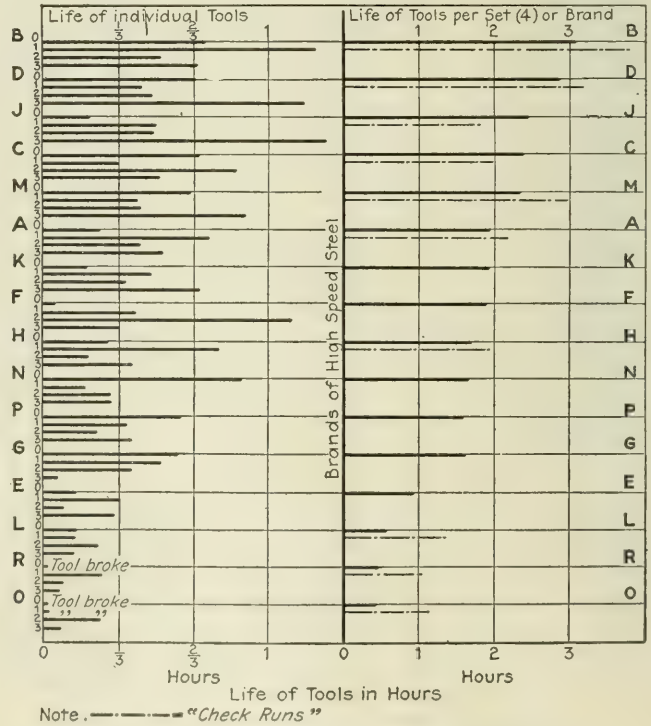

FIG. 6. CURVE SHEET OF SECOND RUN

Turning Liberty motor cylinders 5½ in. diameter. Tool with $\frac{3}{4}$-in. radius nose; cutting speed, 35 ft.; feed, 0.090 in.; depth, $\frac{5}{32}$ in.

at any time and probably would average even better. Brand M, on the other hand, showed a marked improvement in the check run, in which feature it far surpassed brands J and C and was awarded third place for this reason.

It is to be noted that one of these two "superior" steels, i.e., D and B, was in use at the Packard factory previous to the test. As a matter of fact the particular brand in question had been adopted as the factory standard for all Packard-made cutting tools. It should be further emphasized that unlike many large factories, tool steels are here specified by the mechanical department—which department is solely responsible for all machine and tool equipment used in the plant—rather than the purchasing department. This condition reflects credit on the head of the manufacturing department and his staff from the standpoint of industrial engineering.

Comparative Ratings by Other Large Consumers

It was thought expedient about this time to compare these results with those obtained by other large manufacturers. In Table VIII are given data collected with this end in view, the notation in each case being identical with the same symbols as were used in the test. The firms represented are composed of six large automotive manufacturers and three important tool companies. It will be noticed that three of the eight concerns represented buy their steel on the basis of results shown in actual test runs, one company on the basis of analysis only, and the four others on the basis of popular opinion. Note the fact that in the three cases where a cutting test was conducted, brand B was the winner. Further, in one of these instances brands M and D finished second and third respectively; in another, brand D was second and M fourth; while in the third case no mention is made of the other brands, besides B, that were in the test. These data were much appreciated because they verified the findings given in the Packard test to determine the correct choice of really superior steels and also presented some interesting facts about the brands as a whole.

Costs as Affected by a Superior Brand of Tool Steel

Automobile manufacturers usually make but a small percentage of the cutting tools required in their plant. Whenever possible, a standard tool is used, for example milling cutters, end mills, counterbores, hollow mills, reamers, taps, dies, twist drills, etc., and these are secured from companies which specialize in their manufacture. In the same way there are concerns which specialize in the manufacture of special cutting tools, and they in turn satisfy the requirements of the automobile manufacturer. This distribution then obviously effects the greatest economy that can be achieved and also tends to make a uniformly good product. However, some tools must always be made in an automobile manufacturer's own plant, and the annual cost of high-speed steel for this purpose (as it comes from the steel mills) in a factory employing 10,000 men is about $125,000. A plant employing 20,000 men requires about $250,000 worth of high-speed steel, and larger or smaller factories are affected in the same proportion. The cost of the finished tools made from the first amount of steel ($125,000 worth) would be approximately $375,000.

So far, though, these figures show only relative values of the tools. As pointed out in a foregoing paragraph, the tool made from a poor steel may break during hardening, or if it gets into the machine shop it will then give extremely poor results in performance. During rush periods, assuming no excess finished goods in stock, such tool trouble, when occurring on major units like cylinders, crankcases or crankshafts, means that just so many less motors or finished cars can be shipped on that day and production cost is increased accordingly. All of these costs, however, are chargeable to the poor quality of high-speed steel that has been used. It is difficult to say to just what extent manufacturing costs will be affected, but aside entirely from the losses in indirect labor, material and burden that occur when a finished tool of poor steel breaks in hardening, the writer feels that a superior high-speed steel will easily decrease the direct labor cost from 5 to 10 per cent.

TABLE VIII.

Brands of high-speed steel being used by six large automotive manufacturers and three tool companies, and the sequence of their ratings in each case

Name of Co. or Manufacturer	Brands Being Used	Brands Tried	First Choice	Brands in Sequence of Desirability	Undesirable	Remarks
a	B H A J R D M	B C H N A O R D M	B	B D H M A J R	None	These classifications are the results of an actual cutting test.
b	R G B C	R,O G B C,N	R	Non-committal	N O	No test had been conducted in years
d	B C	B C	B	B	None	In a test recently completed, B proved superior to all others and will be used exclusively
e	J L C W	J L C W	J, W & L	Non-committal	None	All high speed steel is bought on the basis of analyses
f	F J L B C	F J,M L,X L,B C	Non-committal	Non-committal	H N X*	Analysis is specified but used as an indicator only
g	D B E M R Y*	D,Y B,J H M,C R,O N	B	B M D H Y* R	C O N J	Standard analyses as specified by the steel maker is requested. Classification is made on the basis of actual cutting tests.
h	C N D A	C N D H	A and H	Non-committal	None	Classification based on opinion only
j	F O N M	F N O M	Non-committal	Non-committal	None	No test had been conducted for five years
m	C N O R	C N O R	C and N	C N O R	None	Classification based on what most of the executive heads of departments thought about the brand

*N and Y are brands of steel that were not represented in the test; they are obviously of inferior quality.

To give a better perspective of the cost and number of tools required to carry out a gasoline motor manufacturing program, the following figures are quoted from the text book of lectures used in the "Advanced Training School"[1] of the Packard Motor Car Co.:

"The total number of tools made by the Packard Motor Car Co. for the Liberty '12' airplane motor was 1,796,910. The cost of the perishable tools only was $1,466,540. Standard tools, such as drills, reamers, counterbores, taps and dies, cost approximately $700,000.

"We used 48,000 special tools for machining the connecting rods, 42,862 of which were perishable tools. For the large cutters which were used for straddle

[1] Edited by D. G. Stanbrough, general superintendent, Packard Motor Car Co.

TABLE II. COMPOSITION AND HEAT TREATMENTS OF TOOL STEELS TESTED

Brand	Chemical Composition * Carbon	Tungsten	Vanadium	Nickel	Chromium	Cobalt	Uranium	Heat Treatment: Preheating	Hardening	Quenching Medium	Drawing Temperature	Remarks on Heat Treatment
A	0.79	12.8	1.74	0.10	3.78	None	None	All tools slowly preheated to 1550-1600 F.	The temperature in the hardening furnace was maintained at practically 2300 F. The tools were withdrawn and quenched when the condition of sweating was satisfactory to the expert representing the steel company which produced the brand being hardened.	Oil	1050	Cyanide on tip of tools during hardening.
B	0.64	16.9	0.92	0.10	2.42	None	None			Lead at 1050 F.	1100	"B" tools withstood the high heat very well.
C	0.40	18.00	0.51	Tr.	3.53	None	0.11			Lead and kerosene.	1050	Tools 0 and 1 quenched in lead. Tools 2 and 3 quenched in kerosene.
D	0.62	14.86	1.05	Tr.	3.59	None	0.10			Lead at 1050 F.	1100	One-half of tool immersed in lead. Relatively short heat.
E	0.49	17.35	0.23	Tr.	2.78	None	0.14			Lead	1100	
F †	0.67	19.70	0.99	0.21	3.78	None	None			Oil and lead	1100	Tools 0 and 1 quenched in lead.
..	0.65	15.79	0.49	0.24	3.44	None	None				.....	Tools 2 and 3 quenched in oil.
G	0.62	18.26	0.75	Tr.	3.70	None	None			Oil	1050	
H	0.66	18.30	0.45	None	4.17	None	None			Lead at 1050 F.	1075	
J	0.68	18.12	0.48	Tr.	2.63	None	0.10			Oil and lead	1050	Tools 0 and 3 were immersed half way in oil; then they were placed on the floor and thus drawn.
K	0.59	13.34	0.95	Tr.	3.64	None	0.15			Oil	1075	
L	0.76	21.92	1.05	None	5.27	None	None			Lead at 1050 F.	1050	
M	0.69	16.95	0.75	0.18	3.09	None	None			Oil and kerosene	1100	Tool 2 quenched in oil. Tools 0, 1 and 3 quenched in kerosene. "M" tools withstood the high heat very well.
N	0.66	13.55	2.20	0.10	3.59	None	None			Oil	1050	
O	0.67	13.50	0.99	0.20	4.30	None	None			Oil and lead	1100	For tool 0 only. Tools 1, 2 and 3 were not drawn.
P	0.38	15.27	0.05	0.20	2.85	None	0.14			Lead	1100	Blistered on heating.
R	0.65	17.08	0.58	0.20	2.78	None	0.10			Oil and lead	1075	Tools 0 and 2 were quenched in lead. Tools 1 and 3 were quenched in oil.
13, 14‡	0.75	11.12	2.10	0.32	5.13	None	None				.....	

The samples for chemical analysis were obtained from the same section of the bar of which the tools were made.

The temperature of the lead bath used in quenching was maintained at a temperature of 105 F. The tools were immersed in the molten metal for about 3 min., and then allowed to cool in the air.

* Phosphorus and sulphur below 0.04 per cent in all cases.
† The second analysis under F gives that of a second bar obtained subsequently.
‡ This steel was not tested, but its microstructure is shown in Figs. 13 and 14.

milling the large ends of the connecting rods, there were 25,000 cutter blades costing $4 each. Eighteen hundred end mills were used for milling out the channel of the rod, and 4,100 doming tools for the cylinder."

It will be observed that the total cost of special and standard cutting tools required for producing the Liberty motor at the Packard Motor Car Co. was $2,000,000 in round figures. One item alone, that of the cutter blades for straddle milling the large ends of the connecting rods, cost $100,000. The tremendous importance of using only the cream of superior grades of high-speed steel is, then, readily perceived, but we must not forget that these figures involve only indirect factory costs. As was pointed out repeatedly, the real inefficiency is not reflected in the tool costs but in the direct labor costs and in a degree far in excess of that indicated by the above figures.

Preferred Chemical Analysis

About the first factor usually determined when a test is to be conducted on a large scale is that of the chemical composition of the different brands. By an inspection of Table II reproduced herewith an astonishing and entirely unwarranted variation of the proportion of the elements well known today as requisite is disclosed. The carbon content varies from 0.38 to 0.79, tungsten from 12.8 to 21.92, vanadium from 0.05 to 2.20, chromium from 2.72 to 5.27. Phosphorus and sulphur were below 0.04 in all cases, while other elements were present in practically a "trace" only. Uranium was probably present in an appreciable quantity in brand D only, the other traces being due to difficultly separated impurities. It is to be noticed that no cobalt or molybdenum was used by any of the steel makers whose brand was represented in the test.

Quite a variation will be observed in the heat treatment of these tools. Table II also contains the details of the heat treatment and such notes on observations as were made. It will be observed that some of the tools of the same brand were treated differently, though this applied only to the kind of quenching medium used and variations in the drawing temperature. On the whole, however, such practice indicates an apparent uncertainty on the part of the steel makers as to which treatment is the best for general purposes or even for a specific requirement.

Regarding the desired chemical composition, the writer feels that the following analysis is probably the most desirable for modern high-speed steel. Alongside is also affixed the analysis of the best high-speed steel tested by Frederick W. Taylor when he wrote his classical monograph "On the Art of Cutting Metals." It shows that this master has apparently plumbed the depth of the art, so that the last fifteen years show little progress in new compositions. As a matter of fact, Taylor recommended an ideal composition, slightly different from the one listed as giving him the best results.

	Minimum	Maximum	Taylor's Best Steel
Carbon	0.62	0.68	0.67
Tungsten	17.00	18.20	18.0
anadium	0.85	1.05	0.29
Chromium	3.00	4.50	5.5
Silicon	0.20	0.30	0.04
Phosphorus	0.00	0.04	Low
Sulphur	0.00	0.04	Low
Other impurities	0.00	0.10	
Manganese	0.00	0.00	0.11

Of course, were a substituting element such as molybdenum, uranium or cobalt used, the composition will be varied accordingly.

Microstructure of Annealed Steels

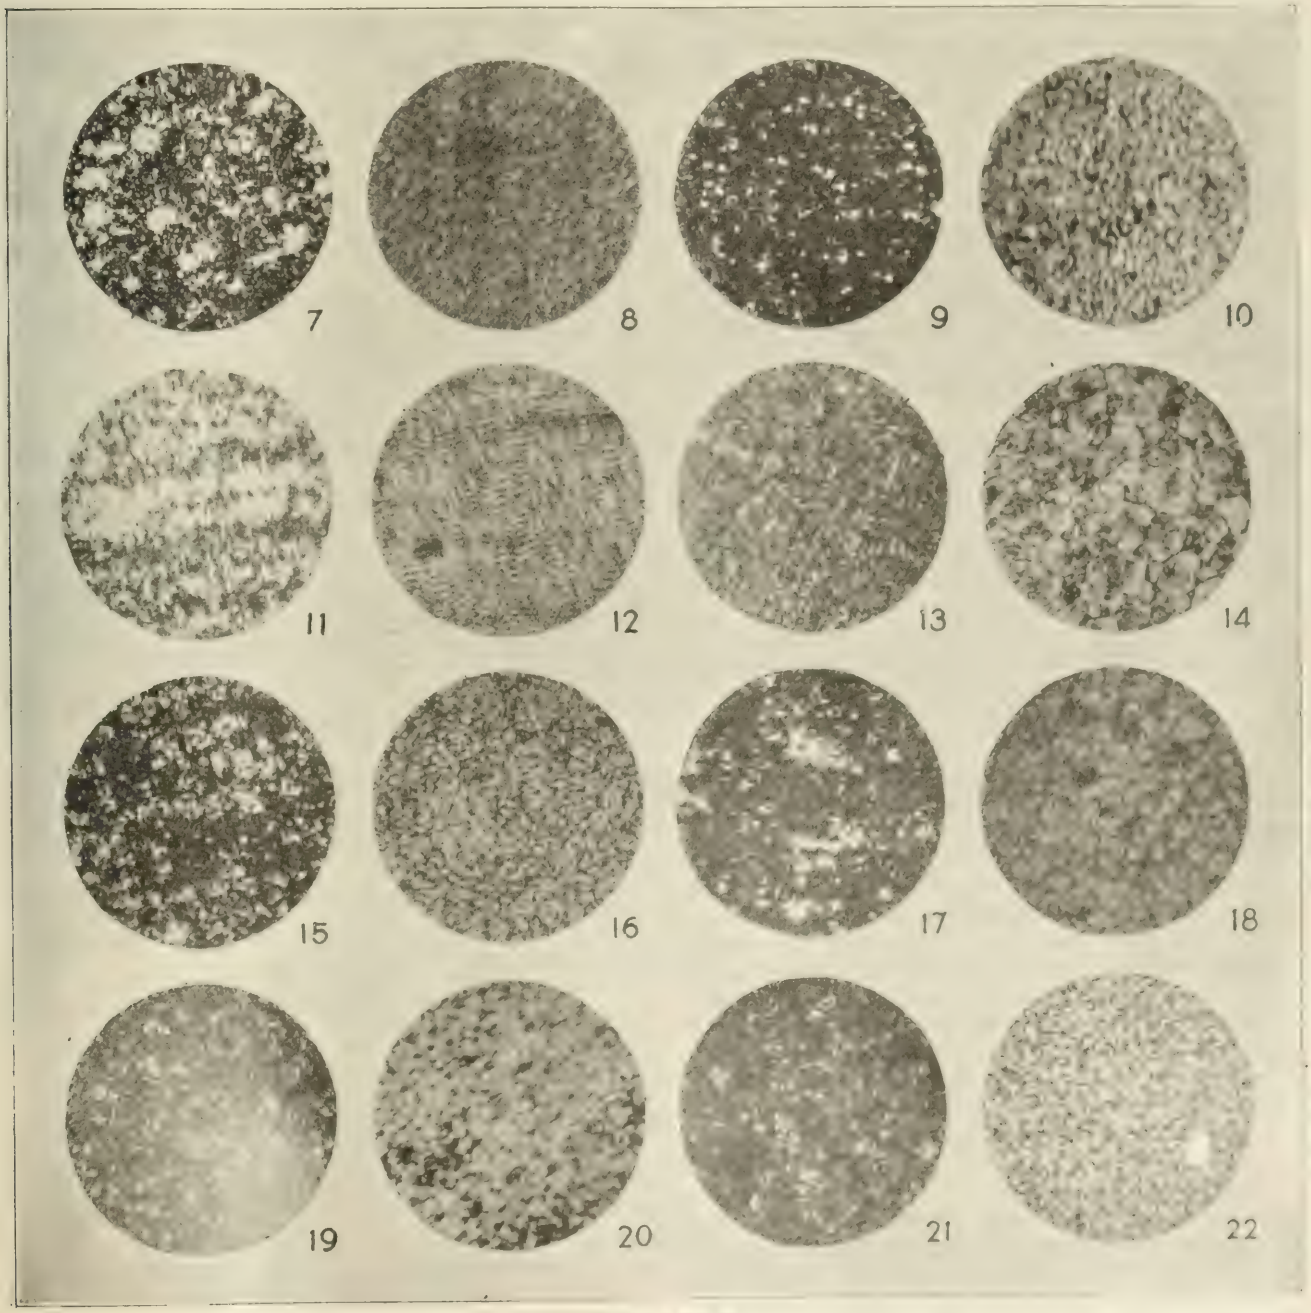
In order to determine the variation that might exist in the microstructure of the various brands of high-speed steel used in the test, specimens were examined

both in the condition in which they were received and also after hardening. It is understood, of course, that these specimens were made from the same section of the bar as were the test tools proper. The hardening of the samples used for microscopic examination was performed by an expert workman of wide experience in the hardening of high-speed steel. In every case the hardening specifications as quoted by the steel manufacturer were used. None of the samples was drawn, because it was desired only to investigate the structure resulting from the prescribed treatment at the high temperature.

Photomicrographs depicting the structure of seven different brands (both in the annealed state as received from the mills and after hardening) are shown in Figs. 7 to 22, all at 100 diameters.

In the case of brand F four exposures, 7 to 10, include a second pair made from a short piece cut from a bar secured from a different source. The cut of pictures as well as the analysis, Table II, shows clearly the wide variations that may be met in this brand.

An inspection of the odd-numbered microphotographs, showing the steel as it came from the mills, indicates that it was all in an annealed state; no trace is exhibited in any of the specimens of the original cellular ingot structure found in the newer cast high-speed steel. The microstructure therefore shows the presence of free carbides bedded in a sorbitic matrix. However, the quantity and the distribution of the carbides differ greatly in the various brands. The amount of free carbides, of course, depends on the composition and the rate of cooling. In the following brief discussion only the general characteristics exhibited in the different microphotographs will be noted.



FIGS. 7 TO 22

Microstructure at 100 diameters after nitric acid etching of same typical high-speed steels. Odd numbers are steels as received, even numbers the corresponding steels after hardening. Figs. 7, 8, 9 and 10 are of brand F. Figs. 11 and 12, brand A. Figs. 13 and 14, brand O, low W. Figs. 15 and 16, brand O. Figs. 17 and 18, brand E. Figs. 19 and 20, brand M. Figs. 21 and 22, brand H

Figs. 7 and 9, as remarked above, are of one brand (F) and therefore probably underwent the same cooling. However, the quantity of free carbides shown in Fig. 7 is much higher than that in Fig. 9. This difference is explained by the higher percentage of tungsten in the former case. In Fig. 11 it will be seen that the carbides are most conspicuous and the chemical analysis (brand L) shows the tungsten in this instance to be the highest of all steels tested. Again in Fig. 13, a bar of brand O in which the tungsten dropped to 11.12 per cent, little free carbide is found. Several of the specimens having good percentages of carbon and tungsten do not reveal corresponding amounts of the free carbides. Probably in such instances the rate of cooling was faster or perhaps the time at the annealing temperature was shorter.

In several instances the distribution of carbides is found to be quite non-uniform. This is brought out exceptionally well in Fig. 11 and Fig. 15. The carbides as depicted in these two cases are obviously more or less segregated into striations, whch indicates that the annealing was not sufficiently prolonged. An inspection of Fig. 12 discloses that even after hardening at the high temperature, this marked segregation of carbides still persists.

Microstructure of Hardened Steels

The exact nature of the physicochemical changes which take place in the hardening of high-speed steel are not yet fully known. Up to the present time no theory has been advanced which satisfactorily explains all the phenomena exhibited by the heating and cooling curves of this steel.[2]

However, it is known that for the best results in hardening, two requirements should be fulfilled. One of the requisites is that the carbides must first be taken into solution and then held in that state by a proper rate of cooling. The second requirement is that the solution of the carbides should be effected in such a manner that the resulting grain size is held to a minimum.

In carbon steel and in most alloy steels the preceding requirements are fulfilled at nearly the same temperatures. In other words, the carbides go into solution at about the same temperature, which also gives maximum grain refinement. This, however, is not true in high-speed steel. Here the temperature at which the carbides go into solution is far above the grain-refining temperature. Since both temperature and time are functions of the grain size, it is imperative that the tool, after thorough pre-heating, be brought rapidly to the high heat and held there for a minimum of time. Otherwise the grain structure will become too coarse and brittle, with consequent fragility. Some of the alloying elements in high-speed steel, tungsten in particular, tend to make grain growth more difficult, an influence on the grain size very beneficial to steel requiring high hardening temperature. On considering the variables which enter into the hardening process, and the difficulty with which they are controlled, the folly of drawing conclusions from tests made with a single tool is evident.

Examination of the photomicrographs of the hardened specimen shows quite a variation in the grain size. In most instances the nitric acid etching after hardening reveals polyhedral structure, part austenitic, part martensitic. The specimen shown in Fig. 14 shows the largest grain structure. Although the granulation in this instance is large as compared to some of the other specimens shown, still it is not uncommonly met with in commercial hardening. Perhaps in this case the large grain size was occasioned more by the high carbon and the low tungsten than by the temperature and time.

The microstructure of the hardened samples shows that little of the free carbides remained undissolved. Only in Figs. 10 and 14 are appreciable quantities of the carbides to be seen. Moderate amounts of undissolved carbide are believed not to have a detrimental effect on the cutting properties providing the tungsten and chromium contents are normal. Still, when the amount of the carbides is too great, as in Fig. 14, the solution will not be sufficiently complete to give good results.

Facts Brought Out in the Test

1. The chemical analysis of a high-speed steel may be used only as an indicator of its possible qualities.
2. Tools made of a medium grade of steel will work fairly satisfactorily when subjected to a relatively light duty.
3. No two tools of the same brand give exactly the same results, in a cutting test.
4. In conducting a test, no less than four specimen tools should be used.
5. To get the most efficient results from high-speed steel tools they must be operated under heavy duty, and no tests are reliable unless made with heavy cuts.
6. Test tools must be reground once, at least, and then again put through another run.
7. High-speed steel should be purchased only on the basis of performance.
8. A wide variation exists in the cutting qualities of the various brands of high-speed steel that are on the market today, and both indirect (material, labor and burden) and direct (labor and burden) costs are affected adversely when inferior steels are used.
9. Heat-treating practices of today leave wide room for improvement.
10. In hardening, the time factor is probably the important item needing investigation.
11. It is expected that a method of determining the efficiency of high-speed steel by means other than the service cutting test will be developed. Work with the X-ray and magnetic properties are quite hopeful in this direction.
12. It is believed that today the American manufacturers can produce a high-speed steel that is at least equal to the best European brands.

Application to the Small Shop

As was pointed out in the opening paragraph of this article, the proper choice of high-speed steel brands is of equal importance to the large manufacturer and the small shop. The writer is convinced that the time is not far distant when even the largest manufacturers will not only use a superior brand for the tools they make themselves but they will, in addition, prescribe the particular brand or a series of brands to "tool shops" that must be used in all the tools manufactured for them. This would apply to standard tools such as milling cutters, counterbores and twist drills, as well as for cutting tools of special design.

All tool steel will be specified by the mechanical

[2] See Sauveur, "Metallography and Heat Treatment."

superintendent, and the purchasing department will work in close co-ordination with that office. It naturally follows that a steel salesman with mechanical training and wide practical experience in manufacturing and steel making will be the successful salesman of the immediate future.

Now, then, what about the small machine shop? Obviously, such an institution cannot conduct a test in the elaborate manner described above. It can, however, conduct a thorough test in a small way, and the following suggestions may be helpful:

Some investigators have apparently concluded that a cutting test consisting of running a tool to destruction by "turning off the face" (that is to say, using the cross-feed and not longitudinal feed) of a bar yields accurate results. This, in my opinion, is erroneous. In the first place, at least two variables are introduced—cutting speed and material cut. It will easily be appreciated that under the proposed conditions the cutting speed varies so that at the center of the bar the duty is very low; as the periphery is approached it increases rapidly to an abnormal value. Now, if a tool approaches its breaking-down point while cutting anywhere near the periphery, failure occurs at once. If, on the other hand, a "weary" tool escapes failure at the periphery, it will continue to cut on its next travel out from the center until a high cutting speed is reached, when it will fail suddenly. However, had the previous cut been continued for a short time longer, possibly seconds only, failure would have inevitably occurred. The total life in such a case will vary widely, giving results entirely out of proportion to the facts. Variations in the material cut will also be encountered, as absolute homogeneity cannot be obtained for any great depth. There are other objections of a practical nature, but it is felt the above are sufficient to establish my positions.

The brands used in the small test can be of a limited number, therefore time spent in investigating a product before it is granted entry to the group to be tested is well spent indeed. Usually, two letters of inquiry per brand will be sufficient to classify it definitely. These letters would naturally be addressed to prominent users of high-speed steel who base their choice of brands on the results of actual cutting tests.

A thorough understanding of Taylor's thirteen fundamental variables and important factors brought out in this work, together with proper safeguarding of the human element, is, of course, essential. Stringent means must be employed to insure the correct heat treatment, and to avoid possible damage in hardening. As far as the material is concerned, a straight production job will give entire satisfaction so long as the necessary precautions are taken. A feed of $\frac{1}{16}$ in. or more, depth of cut $\frac{1}{8}$ in. or greater, time for failure of tool to occur twenty minutes to one-half hour, four test tools per brand, provision for at least one regrind, and a reliable record of all the data will round out the requirements. Finally, as much information as possible should be secured from reliable disinterested parties concerning the various brands of high-speed steel on the market.

APPRECIATION

It affords the writer particular pleasure to acknowledge his appreciation of the great assistance of his present and former associates, R. N. Brown, J. J. Long, E. P. Stenger, F. R. Weaver and M. Y. Kaptansky, who have contributed so much of value to this work.

Canada's Productive Power

The productive power of Canada during 1919 was greater than at any previous time in the history of the country, being in excess of $5,000,000,000, or approximately double that of five or six years ago. This total is made up of:

Manufactured goods	$4,015,000,000
Field crops	1,400,000,000
Live stock sold or slaughtered	750,000,000
Milk and dairy butter	165,000,000
Eggs	90,000,000
Fruits and vegetables	90,000,000
Wool	12,000,000
Fisheries	35,000,000
Forest products	175,000,000
Mining	160,000,000

The figures regarding the manufacturing industry are based upon the census covering 1917 and are in all probability under rather than over the mark as applied to current conditions, there having since then been substantial expansion in several branches of the industry. This is particularly true of such important industries as paper and pulp, automobiles, iron and steel, furniture, and textiles. There is also the shipbuilding industry, which has greatly expanded since 1917, as seen from the shipping report issued in the month of March by the Dominion Government, which shows that during the fiscal year 1919 the aggregate tonnage of the vessels built was 104,444 tons compared with 28,638 two years before.

The figures covering field crops, wool, fisheries, mining, and forest products are compiled from various official government returns. Those covering live stock, milk, dairy butter, eggs, fruits, and vegetables are based on the last regular census returns, with conservative estimated allowances for appreciation in market values. The factory output of butter and cheese or of condensed cream, milk, and powder is included under the classification of manufactured goods. Cheese and butter made in the factories of the Dominion now have an annual value, according to the figures of the Statistical Bureau at Ottawa, of $81,657,000, an increase of nearly $6,000,000, compared with 1917; while the output of condensed and evaporated milk and milk powder, as a result of the enormous expansion which has taken place during the last year or two, was recently estimated by the Dairy Commissioner to possess an annual value of $22,000,000.

Development of French Chemical Industries

The figures below give some idea of the increase in the productive capacity of France during the war in chemical substances other than fine chemicals. They are quoted from the *Board of Trade Journal* for April 1, 1920.

Products	1913 Production, Tons	1913 Consumption, Tons	1919 Production, Tons	1919 Consumption, Tons
Sulphuric acid, 58 deg.	1,160,000	1,172,500	2,500,000	1,500,000
Sulphuric acid, 66 deg.	58,000	58,000	1,200,000	
Oleum (fuming sulphuric acid)	6,000	6,000	900,000	25,000
Nitric acid	20,000	18,500	340,000	37,000
Sodium salts	625,000	506,000	800,000	650,000
Liquid chlorine	300		60,000	15,000
Bromine		100	500	700
Calcium carbide	32,000	28,000	100,000	
Caustic potash	7,500	8,000	100,000	
Caustic soda	75,000	90,000	200,000	150,000
Ammonium salts		9,500	250,000	250,000
Nitrate of lime			1,000,000	250,000
Natural phosphates	2,700,000	1,225,000	4,000,000	2,500,000
Superphosphates	1,965,000	1,960,000	2,500,000	2,500,000
Phosphorus	300	10	2,000	

Great strides, the *Journal* states, have also been made in the manufacture of synthetic products, an impetus having been given by the requirements of the war.

The Properties of Powders

AT THE meeting of the Faraday Society held jointly with the London Section of the Society of Chemical Industry on March 1, Dr. T. Martin Lowry, O.B.E., F.R.S., and F. C. Hemmings presented a paper on "The Properties of Powders," which embodied an investigation that had been carried out for the Scientific and Industrial Research Department under the auspices of a committee appointed by the Council of the Faraday Society.

The caking of salts is in general dependent on the presence of a solvent, usually water. The following cases have been studied:

Nitrates

In the case of ammonium nitrate, very hard caking follows the change of state which takes place at 32 deg. C., but this caking can be prevented by very thorough drying. Hard caking also follows upon mechanical disintegration of the warm salt, but this is also attributed to the influence of moisture released during disintegration. Ammonium nitrate crystallized from alcohol shows much less tendency to cake than when crystallized from water. Caking of ammonium nitrate due to mechanical working is only slight when the conditions are such that moisture can escape from the powder.

Sodium nitrate forms a very hard cake when stored in bulk, but this can be prevented by commercial drying, whereas it is precisely this process which gives rise to the most serious caking in ammonium nitrate. This difference is attributed to the polymorphism of ammonium nitrate, which has no analogy in the case of sodium nitrate.

Potassium nitrate, which is less soluble than either of the two preceding salts, may cake during storage, but apparently to a much smaller extent.

Other Anhydrous Compounds

Serious caking is reported to occur, not only in common salt and in soda ash, but also in potassium chlorate, potassium perchlorate, citric acid and tartaric acid. In the last four cases, caking frequently accompanies or follows the grinding of the dried crystals. This is probably due to the liberation of more moisture during grinding, and can be prevented by drying the compound during or after grinding, and packing in a dry condition.

Hydrated Salts

Caking of hydrated salts frequently gives rise to trouble, e.g., in the case of rochelle salt, borax, sodium phosphate and alum. These hydrates cannot be dealt with in the same way as anhydrous salts, since it is difficult to secure complete drying of the hydrate without partial decomposition. The view is advanced that mechanical working of a hydrated salt not merely releases included moisture, but may result in the breaking up of the hydrate similar to that which takes place when the salt is heated, just as the phenomena which accompany the formation of amorphous materials during cold-working may be compared with the effects produced by fusion. Grinding is found to be accompanied by a slight loss in weight which is recovered quickly from the air. It is not thought that this is sufficient to account for caking of the salt, which is attributed rather to recrystallization following on the disturbance of the normal distribution of water which results from the grinding of the salt, just as sodium sulphate may recrystallize in the normal form after being melted in its water of crystallization.

Loss of Sulphur Dioxide During Caking

Sodium bisulphite and sodium hydrosulphite cake on exposure to air, but this is a more complex change, since not only is water absorbed but sulphur dioxide is also liberated.

Contraction During Caking of Copper Sulphate

When powdered anhydrous copper sulphate is exposed to moist air it swells considerably during hydration, but the absorption of the final 1 per cent of water is accompanied both by caking and by strong contraction. The slight excess of water taken up by the blocks is quickly lost in a dry atmosphere when hydration and caking are complete. Caking and contraction in this case are believed to be due to the simultaneous presence of particles of the trihydrate and of water saturated with the pentahydrate, in which the trihydrate dissolves and crystallizes out again in the ordinary form. The caking of hydrated salts can be prevented by the presence of a small amount of a lower hydrate, which absorbs the traces of moisture which are so effective in producing caking in a salt which is almost fully hydrated.

Attention is directed to the disintegration which accompanies the change of state of ammonium nitrate when dried by heat and which is also observed in the dehydration of many hydrated salts. This disintegration may be used as a substitute for grinding, just as in the converse process of slaking lime by the addition of water.

Dissolution of Belgian Steel Cartel

Much interest has been aroused in industrial circles by the virtual dissolution of the steel producers' cartel (Comptoir des Aciéries Belges), which in prewar days was such an important factor in the Belgian steel industry and included such large works as the Cockerill, Providence. Ougrée, Athus-Grivegnée, Boël, Clabecq, Châtelineau, Espérance-Longdoz, and Thy-le-Château companies. The functions of the association were very important, including the fixing of prices for finished as well as semi-finished products, allocating orders among the various members and serving as intermediary between producers and purchasers at home and abroad. There is some talk of reorganizing the comptoir on former lines, but at least one important concern has announced its unwillingness to enter into a new combination.

The association, it appears, will continue to exist, but its functions are now confined to the receiving of orders, without authority to accept them for individual firms or to fix prices.

It is predicted that the organization will not last long in its present form, as its functions will tend to become purely formal. It is probably that the disorganized state of the Belgian metallurgical industry since the war has had much to do with the dissolution of this powerful syndicate. The dissolution of the cartel has not the same significance that it would have in a period of stabilized prices and normal production and demand.

The Fixed Nitrogen Research Laboratory

A Brief Statement With Illustrations of the Government Investigations Being Made on the Cyanamide, Haber and Arc Processes for Producing Fixed Nitrogen— National Aspects of the Problem

BY ARTHUR B. LAMB*

THE disposition of the experimental Haber plant at Sheffield and the huge cyanamide plant and water-power development at Muscle Shoals, Ala., has been a serious problem confronting the War Department since the conclusion of hostilities.

On the one hand, these plants must be maintained in a state of instant readiness and efficiency in order to afford the military security which was the chief motive for their erection. Again, they represent a great monetary investment which the Government cannot afford to abandon or neglect. Finally, their operation would furnish a supply of cheap nitrogen which would help, at least in some measure, to meet the ever-increasing fertilizer requirements of our country.

On the other hand, the present products of these plants—namely, lime-nitrogen, ammonia and ammonium nitrate—are not immediately salable in large amounts for fertilizer purposes, either because of their intrinsic disabilities or because of the unfamiliarity of our farmers with their use.

Research Laboratory Established

To study these latter problems and because the knowledge of the fixation of atmospheric nitrogen is of vital importance to the military and economic welfare of the nation, and for other reasons, Arthur Graham Glasgow, fixed nitrogen administrator, in the spring of 1919 established the Fixed Nitrogen Research Laboratory, under the supervision of the Nitrate Division of Ordnance, with Dr. Arthur B. Lamb as director and Dr. Richard C. Tolman and Dr. William C. Bray as associate directors. The present staff (April 15, 1920) consists of a total of 108 persons, 77 on the technical staff and 31 on the business staff.

The laboratory is located at the American University, Washington, D. C., where it occupies a number of buildings, the largest of which is the Ohio Building, with a floor space of 50,000 sq.ft. These buildings, together with a large amount of scientific and technical equipment, were transferred to the laboratory from the Research Division, Chemical Warfare Service. Except for the limited technical and industrial facilities of the city of Washington, the laboratory is excellently located. The floor space is ample and the apparatus and equipment are unusually complete. Moreover, the location of the laboratory in Washington makes it possible to carry out important work in co-operation with the Department of Agriculture. Five men from the Bureau of Soils, including several who have had long experience in nitrogen investigation, are giving practically all their time to the work of the laboratory. Many tests on growing plants, both in pots and on $\frac{1}{20}$-acre and $\frac{1}{40}$-acre plots, are also being carried out in co-operation with the Bureau of Plant Industry.

The smaller, partially completed Haber plant, U. S. N. P. No. 1, at Sheffield, Ala., never operated on a commercial basis; the large cyanamide plant, U. S. N. P. No. 2, was practically complete when the armistice was signed, and although now closed down, has been in full operation and has produced thousands of tons of product. Every part of it is well designed and functions successfully, and the whole is undoubtedly not only the best but the largest cyanamide plant in the world, with a capacity of either 220,000 tons of cyanamide or 110,000 tons of ammonium nitrate yearly.

Utilization of Cyanamide

The first problem of the Fixed Nitrogen Research Laboratory has been to investigate methods for the agricultural utilization of the products of this plant. This is a problem with many angles, since cyanamide, the primary product, is a form of fixed nitrogen which at present has in America only a limited use in agriculture, and the many possible ways of increasing its use, as well as the many other forms of fixed nitrogen which can be made from it, must all be investigated. Researches along these lines have included such prob-

lems as the oiling and hydrating of lime-nitrogen to reduce its undesirable properties, the granulation of cyanamide, the mixing of cyanamide with basic phosphates, the production from lime-nitrogen of a non-basic fertilizer containing urea, and the production from lime-nitrogen of ammonium sulphate, ammoniated superphosphate, ammonium phosphate, pure urea, ammonium nitrate and various double salts of ammonium nitrate. It is believed that such researches will make possible a decision as to the best methods by which this great plant at Muscle Shoals can best serve the peace-time needs of this country.

Development of N-H Catalyst

The other Government plant, U. S. N. P. No. 1, using the Haber process, has never operated satisfactorily. It represents, however, a much smaller investment than the cyanamide plant and can undoubtedly be made to operate with further study and research. The problem of the first importance in connection with it is the discovery of a robust and active catalyst for the reaction between nitrogen and hydrogen. The remodeling of the whole plant will be dependent on the ultimate choice of this catalyst. A further important problem in this redesign is the question of the best method of removing ammonia from the circulating system, and this is being investigated at the Fixed Nitrogen Research Laboratory by a group of investigators from the Bureau of Soils, working in co-operation with the staff of the laboratory. A third problem of considerable importance for the redesign of this plant is the study of those alloys of steel which are best adapted to withstand the high pressures, high temperatures and action of ammonia encountered in this process. Work along these lines is under way.

Arc Fixation Studied

Besides the above problems which are determined by the desirability of putting the two Government plants into operation, problems of less pressing importance are being studied, such as improvements in the methods of operating cyanamide plants, and the theory of the fixation of nitrogen by the electric arc. This latter process, although of considerable commercial importance where the very cheapest electrical power is available, is at present of importance in America only from a military point of view, because of the possibility

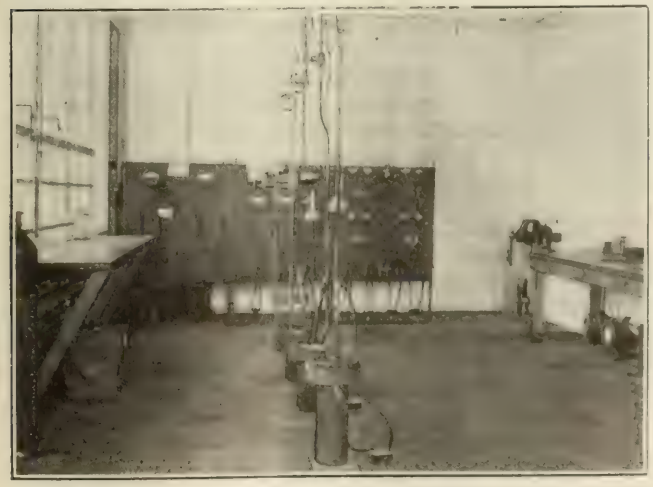

FIG. 10. TWO HABER CATALYST BOMBS AS FIRST INSTALLED

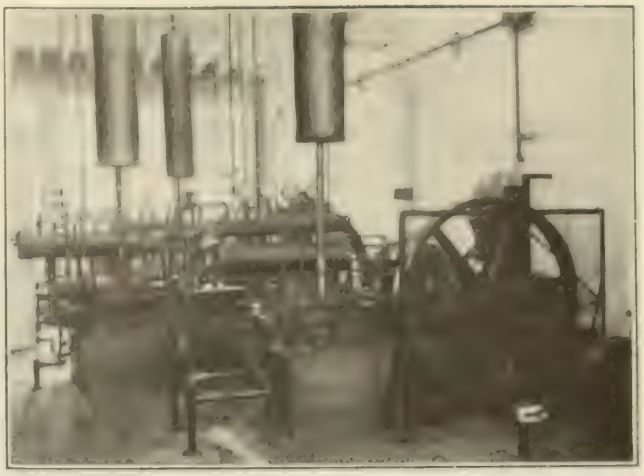

FIG. 11. COMPRESSORS FOR AMMONIA SYNTHESIS

of its rapid installation in time of emergency. A fundamental investigation of the relation between gaseous ionization and chemical reaction, however, may make this process also commercially important in America, and some work is now under way at this laboratory.

Research Situation in Germany

The activity of Germany on nitrogen research is certainly instructive. After years of extensive research and experimentation with governmental support a Haber plant with the very considerable output of over twenty tons of ammonia per day was erected at Oppau in 1913. At the outbreak of the war this was very greatly enlarged. Of all the buildings constructed at that time and in spite of their several years' successful experience with this process, the largest and finest was the Research Laboratory. It is 300 ft. long, 100 ft. wide and five stories high, and is entirely devoted to research. In August, 1919, although the plant was not operating, there were said to be seventy-five chemists at work in this building on research problems; during the war there were said to have been 250 chemists thus engaged.

The future of the Fixed Nitrogen Research Laboratory will presumably depend on legislation now pending in Congress. Senate Bill 3,390 and the corresponding bill before the House, besides providing for a self-sustaining Federal agency to operate the Government fixation plants, also specifically provides for research laboratories and experimental plants for the development of fixed-nitrogen production.

This important field of research certainly needs the resources, the scope and the disinterested point of view which the Government alone can provide.

Washington, D. C.

Industrial Experimental Laboratory in Mexico

On March 1 the Mexican Ministry of Industry, Commerce and Labor formally inaugurated an industrial experimental laboratory in connection with the commercial museum. The new laboratory is complete in every detail and is intended to offer opportunity for instruction in modern processes of manufacture to persons with small capital who are desirous of turning Mexican raw materials into manufactured products. There are in connection with the laboratory fully equipped machine shops, carpenter shops, and tin shops, with a corps of instructors for each different department.

Legal Notes

By Wellington Gustin

Contract Under War Provision Upheld

A contract, cancellation of which was due to the war, has been the subject of judicial interpretation and construction by the Supreme Court of Alabama. Whether the contract was subject to cancellation under the terms of the contract relating to war or whether such cancellation was a breach of contract was in issue between the parties, the Capital Fertilizer Co. vs. the Ashcroft-Wilkinson Co. (79 So., 484.)

The facts on which the action was founded are succinctly stated as follows: The plaintiff claimed $30,000 damages for breach of a contract entered into on May 25, 1914, by the terms of which the defendant sold to plaintiff 1,485 tons of potash, manure salts and kainit, for deliveries in November, 1914. In the second count of his complaint plaintiff claimed $3,500 for breach of a contract, entered into on July 11, 1914, for the sale of 200 tons of manure salts. Both contracts contain a clause providing: "It is understood that in case of war, rebellion or any interference by either the American or foreign government, strikes, accidents, epidemics or other contingencies happening to one or more of the mines or works furnishing or shipping the goods . . . then the seller has permission to cancel this contract."

War Set Up as Defense

In his defense the defendant set out that since the execution of the contracts one of the contingencies named as a ground for cancellation of the contract has happened, namely, that on Aug. 1, 1914, war broke out in Europe between the German Government and those of England, Russia and France, and, subsequently, on the seventh day of October, 1914, the defendant cancelled the contracts in writing.

The products of potash, manure salts and kainit were to be imported from foreign mines, by inference from the country of Germany. The contract provided for a differential duty or charge imposed by the United States or German Government, and that the foreign analyses furnished by the mines should be binding.

Contentions of the Parties

On the appeal from a judgment against it in the lower court the plaintiff contended that under the terms of the contract here in question the defendant could cancel the same only in the event of war which proximately prevented it from performing its contract; and that to construe the contract as giving the absolute right of cancellation in the event of war anywhere, without regard to its effect upon the ability of the seller to comply with its terms, would be both unusual and unreasonable. In opposition the defendant contended that the parties have, by the language used, created an absolute option to cancel the contract upon the happening of certain specified contingencies, one of them being "in case of war," and that the parties "meant what they said and said what they meant" when they placed this absolute option in the contract; that it means war—any war, anywhere; that in using the language plain and unambiguous, the parties have exercised the constitutional freedom of the contract, and they had the right to specify the event of any war anywhere as a signal for a right to cancel on the part of the seller."

The defendant strenuously insisted that the plain and unambiguous language of the absolute option given the seller in the contract was not open to construction—it was, however, urged that, if open to construction at all, it would only be to the extent of ascertaining what war was in contemplation of the parties when the contract was made. The furthest point in such a construction would be that the parties contemplated, by the language used, a war either in this country or Germany, from which country the products were to be obtained.

Court Construes Contract

The cancellation clause refers to rebellion, or any interference by either the American or a foreign government. Besides other alternatives the one here concerned is: "It is understood that in case of war . . . then the seller has permission to cancel this contract." Said the court: "We are of the opinion that this part of the cancellation clause here in question is properly construed as having reference to a war either in this country or in Germany, from which latter country it sufficiently appears the products were to be obtained."

This point being determined, the next point for consideration was that urged by the plaintiff that the war, within the meaning of the words in the cancellation clause, must be such that it becomes the proximate cause in preventing the seller from performing the terms of the contract.

Now there is a class of cases in which the language used in the contracts indicates that the contracts were made either subject to or contingent upon strikes, accidents or contingencies beyond the seller's control, and necessarily required construction to ascertain the meaning. But in the language quoted above the seller is given the absolute option to cancel the contract in case of war.

The court said that the effect of the war in Germany or in this country upon the ability of the seller to comply with the contract here was an unknown quantity, as well as its effect upon the transportation of goods, the risk incurred, the price of goods, and the freight rates; all of these in case of war are left in a state of uncertainty. It is not merely the question of ability to obtain the goods, but also the question of the great risk, in the happening of such events, both as to prices and freight rates. "We think, upon consideration, that the cancellation clause was not without some reason and business sagacity for its foundation, and that it was inserted for the seller's protection and with a sense of business prudence."

Contract Obligations Defined

In a cited case the court said: "The contracts of men are laws prescribed by themselves to govern their transactions with each other, which, as long as they interfere not with morality or with the interests of third persons, are conclusive obligations on the immediate parties to them."

It was a part of business sagacity that seller had the cancellation clause as to war, in the broad and sweeping terms "in case of war," so written in the contract. The right to cancel arose as soon as war occurred in Germany, whether such war was the proximate cause of any inability to perform on seller's part or not.

Diatomaceous or Infusorial Earth*

By W. C. Phalen†

DIATOMACEOUS earth is more commonly known as infusorial earth, and is sometimes referred to by its German name "kieselguhr." It is also, though erroneously, called tripoli. It is composed of the siliceous remains of minute aquatic plants known as diatoms, which are of minute proportions as a general rule, and have to be identified chiefly by aid of the microscope. The organic matter of these plants has long since disappeared from most of the deposits, but there are notable exceptions, as in California.

These low forms of plant life secrete silica much after the same manner as mollusks secrete lime and thus build up their shells. It is this part of the plant which makes up the formations found in nature. The siliceous parts accumulate on the bottoms of the bodies of water in which the plants lived, and in time attain considerable thickness, and become of economic importance. The diatoms may live in either fresh or salt water, and under varying conditions of depth, pressure and temperature. For example, they have been found in the depths of the Atlantic Ocean, and are known to occur in the warm springs of Yellowstone National Park, to cite two extremes of temperature, pressure and difference in the character of the water. The material is now in process of formation and although it has in times past been formed in very different epochs, it is especially abundant in the Tertiary, and most of the known beds of great thickness are of this age.

Chemical Composition

In chemical composition, diatomaceous earth is a hydrous silica or opal, but as a rule it contains a considerable quantity of earthy impurities. A very simple test, taken in connection with other distinguishing characteristics, is that when touched with hydrochloric acid it does not effervesce. Sometimes analyses from widely separated localities show great similarity of composition; as, for example, the first three analyses in the accompanying table.

ANALYSES OF DIATOMACEOUS EARTH

	1	2	3	4	5	6	7	8

8. Monterey, Monterey Co., California, A. C. Lawson and J. de la C. Posada, Dept. Geol., Univ. Calif., vol. 1, p. 25, sp. gr. 1.8 to 2.1.

Uses

The chief use of diatomaceous earth is as a cleanser and polisher, and for these purposes it is used in the form of a powder or mixed with soap. It is a most effective non-conductor of heat, and has been used alone or with various compounds in covering for boilers, steam pipe, furnaces and stoves, and in the manufacture of fireproof cements.

It has great absorbent qualities, as will be noted from the fact that its specific gravity, bulk for bulk, is only one-third that of water—namely, 0.33. Its absorbent quality makes it suitable for water filters. The statement has often been made in the literature that it has been used in the manufacture of dynamite, but I understand that its use for this purpose has long since been entirely supplanted by wood pulp, on account of the danger from particles of grit. Boiled with shellac, it is used in the manufacture of records for talking machines.

Its uses abroad have been more numerous than in the United States. It had been used in Europe for the absorption of liquid manures so as to make the latter conveniently available as a fertilizer. It has also been used in the manufacture of water-glass, in making cement, in tile glazing, artificial stone, ultramarine and other pigments of aniline and alizarine colors, paper filling, sealing wax, fireworks, hard rubber objects, matches, papier maché, as a container for liquid bromine and for miscellaneous minor purposes.

In California it has been used in the construction of buildings, advantage being taken of its property of being readily cut into any desired shape or size. In some of the California reports, it is referred to as shale. It is easily quarried, and the small blocks into which it may be cut are light in weight and placed easily in position. In powdered form the material has been used to a certain extent in California in the manufacture of plaster.

Preparation of Material

In preparing the earth for industrial use it is first roasted to expel as much water and organic matter as possible. It is then transferred to a furnace and heated to a moderately high temperature, but with the exercise of sufficient care so as not to destroy its porosity by overheating. It is then finely ground between rollers, sifted and sacked to prevent re-absorption of moisture. For certain purposes, it is only necessary to give it a prolonged drying at a high temperature prior to grinding and sifting.

In Santa Barbara County, California, the material is broken in open air quarries and as mined contains a considerable percentage of moisture. After forty to fifty days of drying in the dry atmosphere of southern California, the material still contains a small percentage, approximately 5 per cent, of moisture. Some of the material after air-drying is sawed into bricks or other shapes and dried in kilns. Such bricks are used for insulating purposes. The rest of the material is finely powdered in mills and sacked to be used for filtering. Quarrying is done by electrically driven channeling machines. Some of the California material contains 5 per cent of alumina, presumably in the form of clay, which acts as a binder. This material is adapted to the use of building blocks for interior fireproof walls, and contains about 85 per cent silica.

One of the deposits near Lompoc—namely, that of the Celite Products Co., formerly the Kieselguhr Company of America—comprises extensive beds of soft white earth in a very pure state, both thin and massive. These form a cap over the hills and overlie brown

*From Bureau of Mines Monthly Report on Investigations, March, 1920.
†Mineral technologist, Bureau of Mines.

siliceous shales and are conformable with them. The strike is east and west and the dip is 30 deg. south. This material is being quarried in open cuts. It is taken up in large blocks and air-dried in the quarry. It takes from forty to fifty days to reduce the water content, which ranges from 25 to 45 per cent by weight, to 5 per cent. It is then hauled by motor trucks to the plant at Lompoc, where it is ground to powder and transferred to the different warehouses by a pneumatic system. When blocks are required, the material is transported in its natural state direct from the quarry, sawed to the required sizes, and dried before shipment. The material, when dried, is utilized in making brick, tile and other refractory materials.

The quarry operations are readily carried out where transverse joints occur in the strata due to earth movements. Where these are not present to facilitate removal of the rock, it is necessary to loosen it slightly by means of powder before blocks can be removed from the quarry face.

On account of the quantity of absorbed surface water in the diatomaceous earth, it is necessary that it be split into convenient blocks for drying.

Deposits in the United States

That infusorial earth is a widely distributed commodity in the United States is evident from the descriptions given below. The localities outlined are doubtless far from being a complete list. They are given principally to indicate the widespread occurrences of the material.

Maine: A deposit of diatomaceous (infusorial) earth of unknown extent is reported to have been worked in South Beddington, Washington County. The material is said to be of pure white color and of unknown extent.

New Hampshire: Beds of diatomaceous earth are reported from the vicinity of Lake Umbagog. An analysis of this material is given above.

Massachusetts: Beds of infusorial earth are said to occur near South Framingham.

New York: Two deposits of infusorial earth are known in the State of New York—namely, at White Lake, Herkimer County, and at Cold Spring Harbor, on Long Island. It is likely that careful prospecting will reveal other deposits in some of the larger peat bogs and marshes of the State.[1]

New Jersey: Near Drakesville there occurs a deposit which covers a small acreage to a depth of 1 to 3 ft.

Maryland: Infusorial earth has been mined along Lyons Creek, a branch of the Patapsco River, separating Calvert and Anne Arundel Counties. The location is five miles west of Herring Bay, on the west shore of Chesapeake Bay. Deposits are also known extending from Fairhaven, on Herring Bay, to Pope Creek, on the Potomac River. It occurs at the base of the Calvert formation, which is Miocene (Tertiary).

Virginia: Diatomaceous earth occurs also in the Calvert formation of the Chesapeake group in the vicinity of Richmond, Va. The lower beds of the formation, chiefly those between 5 to 20 ft. from the base, contain diatom remains in sufficient quantity to entitle it to be termed diatomaceous earth. In weathering, the portions rich in diatom remains become nearly pure white. The material is of very fine texture, and is very light gray to white in color. Its lightness is characteristic, having a specific gravity of only 0.33, bulk for bulk. It outcrops especially in the valley of Shockoe Creek. The available material here is not so great in extent as at some other localities in Virginia and Maryland. The purer deposits are soft and clay-like, and when dug are very porous with a white or slightly yellowish tinge.

Florida: The Florida deposits of diatomaceous earth have been formed in fresh water, and are of comparatively recent date. A deposit located at Eustis, which has been worked to some extent, is in general appearance very much like the peat bogs of that section. The diatomaceous earth is in fact intimately mixed with peat or muck, and the material as taken from the bogs looks like peat of a grayish color. The method of treatment is to burn out the carbonaceous matter, leaving the siliceous material as a very fine white powder. The deposit in this bog has a thickness of 20 ft. or more.

About three miles east of Tavares, on the north side of Lake Dora, is a bog of the peat prairie type covering 100 acres. In 1901 a plant to treat the infusorial earth was erected on the north edge of this prairie a few hundred feet from the Sanford and Eustis division of what is now the Atlantic and Coast Line R.R. Besides the occurrence near Eustis, Lake County, a number of samples of similar material have come from Polk County.

It is reported that the Eustis product was at first shipped to England for use in making scouring soap.

New Mexico: Near Socorro there is stated to be a deposit of fine quality which outcrops in one place 1,500 ft. long and with a thickness of 6 ft.

Nevada: A deposit of diatomaceous earth is reported in a railroad cut west of Reno, Nev., with a thickness not less than 300 ft. and varying from a pure white to a pale buff or canary color.

Oregon: Near Linkville, Klamath County, there occurs a deposit of infusorial earth which has been traced a distance of ten miles, and along Lost River it shows a thickness of 40 ft.

Idaho: Beds of diatomaceous earth are known to occur in Idaho.

Washington: Beds of diatomaceous earth are known to occur near Seattle, Wash.

California: There are a number of deposits of infusorial earth in California. The most important thus far developed are in Santa Barbara, Monterey, Orange and San Luis Obispo Counties. The material in Santa Barbara County is of superior quality and has been worked on a commercial scale. Infusorial earth is also found in Fresno, Kern, Los Angeles, Plumas, San Benito, San Bernardino, San Joaquin, Shasta, Sonoma and Tehama Counties. During 1918 five quarries operating in Monterey and Santa Barbara Counties produced a total of 36,000 tons of this material, valued at $190,000. The most important deposit is that of the Celite Products Co., formerly the Kieselguhr Company of America, the name having been changed during the war. The quarry and mill of this company are at Lompoc, Santa Barbara County. This company has rapidly increased the scope of its dust operations, and it is reported that it expects to still further increase them. There is still another operation in the same vicinity by the name of La Salle Canyon quarry. Near Bradley, in Monterey County, there have been two small operations, and possibly a third. The deposits of northern Santa Barbara County have been described in great detail by Ralph Arnold and Robert Anderson in Part I of U. S. Geol. Sur. Bull. 315 (1906).

[1] Parsons, A. L.: "Peat, Its Formation, Uses, and Occurrence in New York," 57th Ann. Rept., N. Y. State Museum, vol. 1, sec. 1 (or 23d Ann. Rept. State Geologist, Part 1); 15-80-1905.

Reliability of Materials and Mechanism of Fractures*

The Focus of Impact Fracture Is Below the Surface Opposite the One Receiving the Blow, and the Metal or Amorphous Substance Splits Along Radiating Surfaces, Overlapping or Separated by Ripples Which Further Out Develop Into Major Fracture Planes

BY CHARLES DE FREMINVILLE†

RELIABILITY is the quality we desire in the metals we use, but it is very difficult to ascertain it through a short test. The reliability of materials is like the reliability of friends. Whatever brilliant qualities they may exhibit, their reliability is known only in the long run, so that in the case of an apparent failure, the qualities of a metal, like those of a friend, should not be questioned too quickly. It is not enough to know the intrinsic qualities of the metal; a very careful study of the circumstances under which the failure occurred must also be made, and it is this fact which has made the study of fractures and of the mechanism of fractures one of great interest to the author.

During the early days of the automobile industry the problem of resistance of materials began to be considered in a new light. The first motor cars that were built were designed with factors of safety then generally accepted for the resistance of medium-carbon steel. But the engineer soon came into contact with the sportsman and was tempted to put into the gearing a stress much greater than the one for which it had been made. One of the problems to be solved, therefore, was to secure a material which could safely be used for gears.

At that time steel makers had produced, among certain other new products, ternary steels, which showed brilliant promises of new qualities if the results of the laboratory tests to which they had been submitted could be taken as a proof of their reliability.

Viewing the question of material for motor cars in a general manner, the constituent parts appeared to belong to two distinct classes. The first included such parts as gears, crankshafts, connecting rods, etc., which had to withstand severe normal shocks. Also only a small amount of wear was allowable and the class of accidents to which they were liable was limited, being chiefly those of seizing or an encounter with stray nuts or bolts.

The parts of the second class did not have much stress imposed upon them in ordinary service, but they did have to meet with what can be termed "normal accidents," and were therefore expected to bend to a certain extent without ceasing to fulfill their duty. To this class belonged front axles and, more generally, all the parts connected with the steering mechanism. For these, the "normal accident" can happen very frequently. It is almost impossible to say that the wheel of a car will not come rather abruptly into contact with a curbstone, or even with the wheel of another car. In such case something must yield or break. It is of course but natural to hope that something will yield and that this yielding has been foreseen; also that it will take place on a piece easily seen and easily replaced, and that the material of which the piece is made will not cease to be reliable.

The impact test, to which attention was directed at that time in France by M. Considère and later by M. Frémont, seemed to be a very convenient method for ascertaining the characteristics of the parts of each class. The impact test, however, was devised primarily for soft steel and had to be adapted for very hard steel. But by making use of the impact test it was possible to select for the parts of the first class a grade of steel which only fractured after a very small amount of deformation, and this could be considered as a very excellent quality for the parts of this class.

The parts of the second class were expected to bend under the impact test to a very great extent, and it was easy to find wrought iron or mild steel possessing this characteristic, although the reliability of these materials for the use considered is a matter open to discussion. But here again the problem became complicated, because there were those who seemed reluctant to admit that some of the parts had to bend easily under certain circumstances and that a limited amount of toughness was not desirable, inasmuch as the steel maker pretended to have grades of steel uniting in a rare degree ductility with toughness.

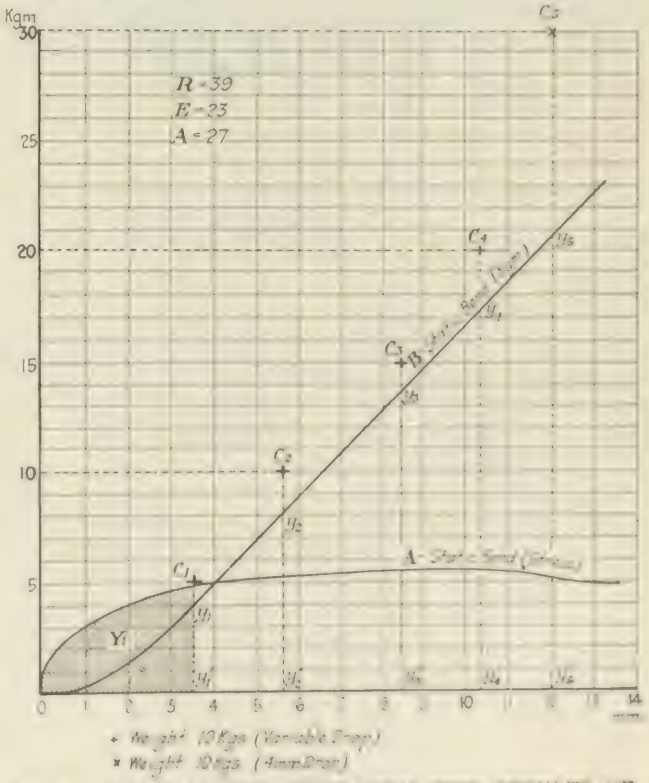

FIG. 1 DIAGRAM FOR COMPARING THE RESULTS OF STATIC BEND AND DROP BEND TESTS

*Presented at the annual meeting, New York, December, 1919, of the American Society of Mechanical Engineers, and printed in their *Journal*, April, 1920. A brief abstract of his address was given in CHEM. & MET. ENG., vol. 21, p. 613 (Nov. 12-19, 1919).

†Architectural and industrial engineer, Paris, France. Consulting engineer, Schneider Works. Hon.Mem.Am.Soc.M.E.

The tensile tests of these steels showed a high ultimate strength and a great elongation. The impact test showed that a considerable amount of energy had been absorbed by the test piece, which gave a great amount of distortion. It is evident that if it had been possible to have a diagram of the impact test, showing at every moment what was the amount of stress corresponding to a given deflection, the matter would have been made very much clearer. But since there was no machine that would give such a diagram, a substitute was found in a static bending machine registering the amount of energy taken in the deformation process. It was possible to ascertain that in all the cases which had to be investigated, the number of kilogram-meters absorbed was practically the same as in a quick bend or in a drop test. So far as the appearance of the fracture was concerned there was no perceptible difference in either case,

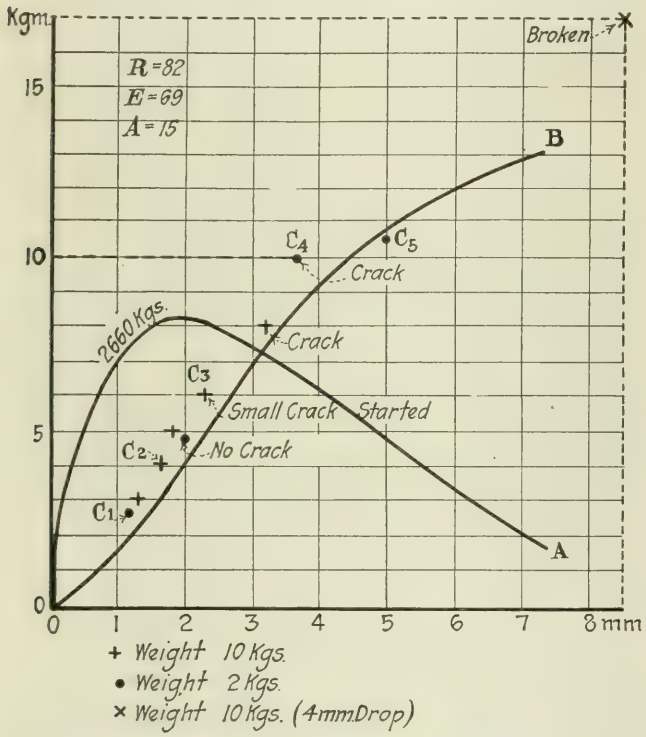

FIG. 2. DIAGRAM FOR COMPARING THE RESULTS OF STATIC BEND AND DROP BEND TESTS

which showed that the metal which seemed to possess ductility and toughness did not possess these characteristics to the extent believed.[1]

Figs. 1 and 2 are diagrams for comparing the results obtained by drop tests and quick-bend tests on notched test pieces. In these diagrams the ordinates of curves A are proportional to loads corresponding to deflections shown on the abscissa scale. In curves B (which are the integrals of curves A,—ordinates $y_1y'_1$, being proportional to surface Y_1, and so on) the amount of energy consumed in the bending test is given for each value of the deflection. The ordinates y'_1C_1, y'_2C_2, etc., are proportional to the amount of energy absorbed by the drop test for the same deflection, as measured in the bend test, and can be easily compared with $y_1y'_1$, $y_2y'_2$. The energy absorbed in the drop test appears to be only slightly greater than that absorbed in the quick-bend test, but the process has followed the same course in

[1]The author has recently learned that the same idea of interpreting a drop test by means of a diagram given by a static bend test has been successfully used in this country for testing rails, and he believes that it can be used in many instances.

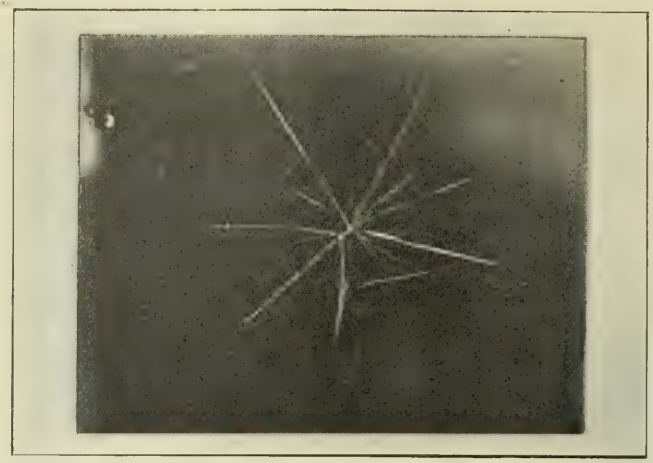

FIG. 3. RESULT OF SHARP SHOCK ON A GLASS VESSEL

both cases, and the difference may be attributed to errors in the experimental work.

Fig. 1 is a diagram of a test of wrought iron or mild steel in which the amount of stress necessary to obtain a given deflection remains constant over a long range. This is the type of material which can be expected to give good results for parts of the second class.

Fig. 2 is a diagram of a test of a steel with a certain amount of ductility, in which the energy consumed for a given deflection appears to be greater than in the case of Fig. 1, and which was offered for parts of the second class. It should be noted that in Fig. 2 curve A is absolutely different from curve A of Fig. 1, as it shows that a maximum amount of the energy is absorbed after a small deflection has been obtained. This maximum is the point where the piece begins to show a crack, which of course did not exist in the test piece whose diagram is shown in Fig. 1.

Parts of the second class made of this metal proved a decided failure. Even without experiencing the "normal accidents" which they were expected to withstand, they showed a great tendency to crack without the slightest deformation, which method of fracture has been called *fissillité* by the late M. Brustlein, of the Jacob Holtzer firm, Unieux, France.

By looking closely into the fracture of the broken test piece, which was supposed to possess ductility and toughness, it could be seen that most of the distortion,

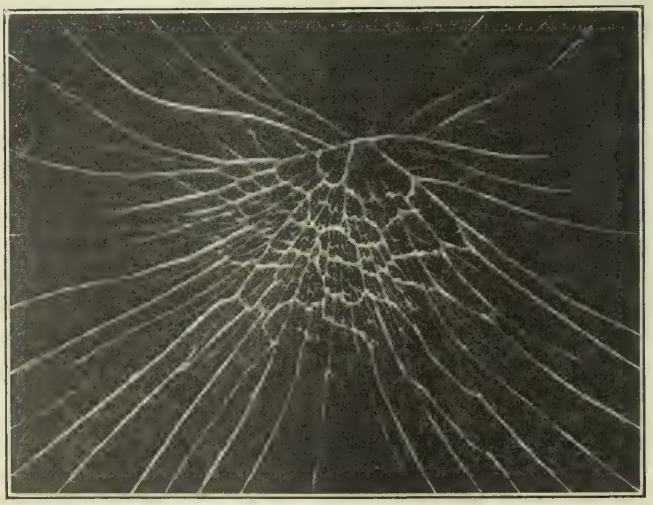

FIG. 4. DEVELOPMENT OF THE FRACTURE RESULTING FROM A SHOCK ON A THIN SHEET OF GLASS

or flowing of the metal, had taken place not before the fracture was started, but during the process of extension of the fracture, and this gave to the amount of energy recorded an altogether different meaning. In this case the failure of the material could be traced to a bad interpretation of the test, but other failures were encountered which could not be traced to the quality of

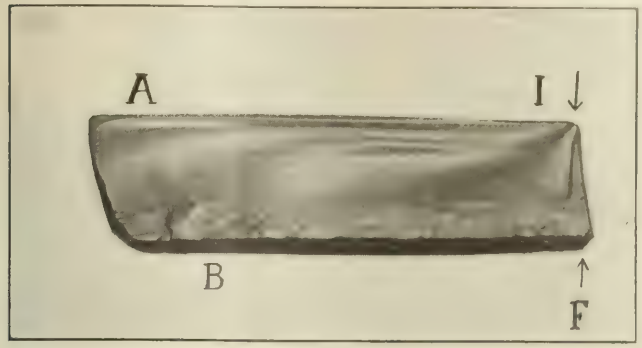

FIG. 5. FRACTURE SURFACE IN A SLAB OF GLASS

the metal used. Typical among these was the sudden snapping of levers, under conditions which could be specified but which were difficult to explain. The impact test, like others, could not give a clue as to reliability in certain circumstances.

The Study of Fractures

The uncertainties in the behavior of material, the propagation of a crack without any distortion of the piece, the sudden snapping of a rod without any perceptible alteration in the neighborhood, even the changes which were produced in brittleness under heat treatment, appeared to be difficult to account for, and it seemed to the author to be worth while to add to the theoretical views of the question by making, as far as possible, a thorough study of the fracture itself, which would tell, in some cases, the story of the failure.

It is frequently believed that fracture is a form of failure of such peculiar character as to escape all rules.

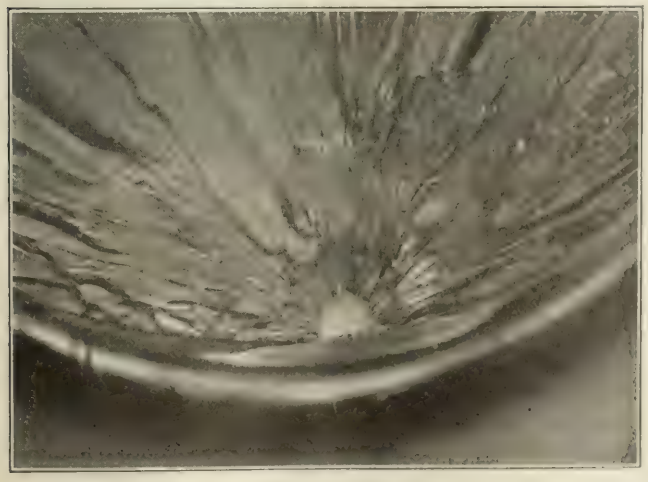

FIG. 6. SMALL SPLINTERING FOCUS GLASS

However, the attention of the author was first attracted by the very regular fractures of sandstone, which is used extensively in France for pavements, and which so resemble one another that they seem to be real diagrams of what has happened during the rupture. Moreover, a certain number of peculiarities of the fractures were found to be common to both sandstone and steel. It was also noticed that these same features were found in glass fractures, in which they could be observed with great accuracy; also that they were still easier to observe in Judea bitumen, where the breakage was produced very easily. A further study has shown that the fractures developed in an identical manner in these various materials.

It is not possible in the limited time at the disposal of the author to go thoroughly into the subject of the study of fractures, and as a result attention can only be called to some of the main features. Fig. 3 shows a fracture developed in a glass vessel by a sharp shock. In this should be noted the symmetry of the surfaces originated and the peculiar disposition of the starting points of these surfaces from both ends of a small line to which the surfaces are tangent. Fig. 4 shows the development of the fracture resulting from a similar

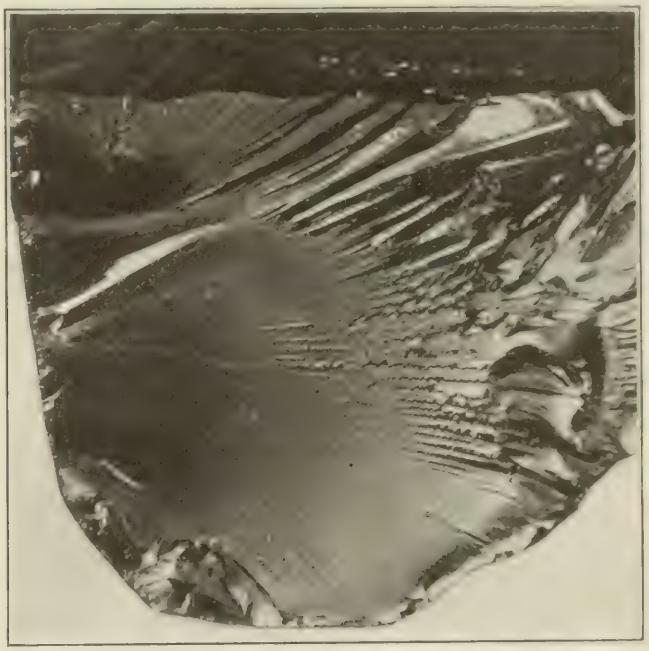

FIG. 7. FRACTURE IN JUDEA BITUMEN

shock in a thin sheet of glass. Here great symmetry is seen, the network also originates from a small line, and some of the surfaces extend entirely through the glass, some only partially.

Fig. 5 is taken from a slab of glass broken in the same manner. It shows one of the surfaces dividing the slab into pieces, which was also partially cut by other surfaces. In this particular case the blow was given at *I* on the top of the slab, and it will be seen that the small line, noted in the previous figures as the origin of all the cracks, is situated at *F* at the opposite side of the surface. It presents a very remarkable appearance and the general disposition of the surface induces us to believe that the fracture originated in that region.

Fig. 6 shows in great detail another specimen, which illustrates very clearly that there is a starting point of the fracture. Many such examples enable us to see that one of the main surfaces cutting the test sample has not expanded at one stretch, but is formed by surfaces overlapping each other like the blades of a fan. This is made still more evident by the fracture shown in Fig. 7. These surfaces overlap each other at distances often smaller than a hundredth of an inch, and by making use

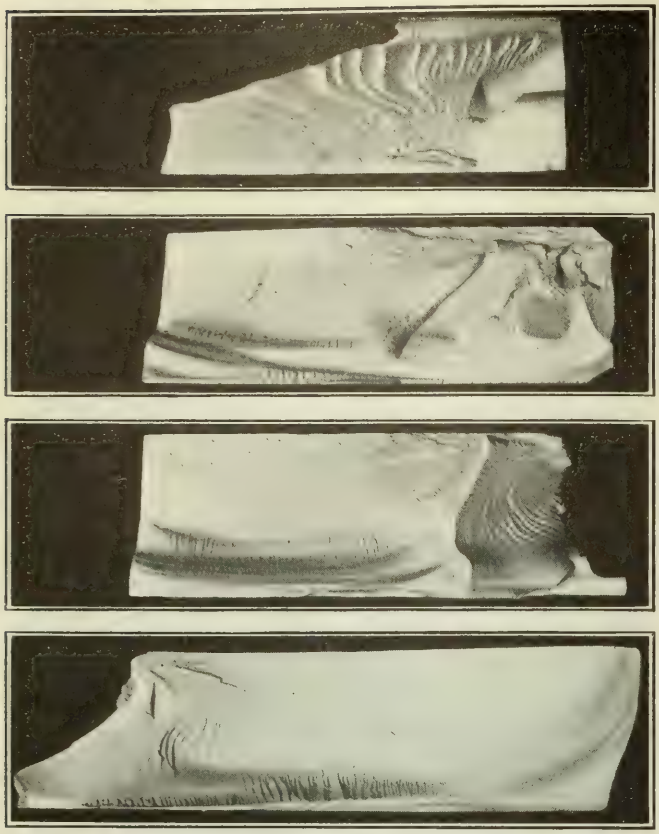

FIG. 8. FRACTURE IN TOOL STEEL

of the method called *recoupement* (recutting) by the geologists, it is possible to follow the successive order in which the various elements of the fractures have developed.

Fig. 9 shows in greater detail one of these surfaces, and enables us to point out some of its special features. Part of the surface is bright and part dull. A study of the bright part can be made from Fig. 7, which shows a standard fracture in Judea bitumen. It is very easy to

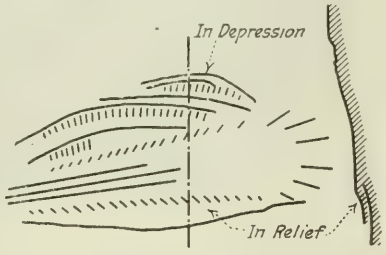

FIG. 9. SCHEME OF FRACTURE IN JUDEA BITUMEN

FIG. 10. RENTS FORMED UNDER THE MAIN SURFACE IN GLASS

follow the surfaces overlapping each other, as is shown by the scheme in Fig. 11. The general arrangement of the surfaces bears a very close resemblance to the surface of water as it runs in a culvert, passes over a dam, or expands in a shallow pond.

The same arrangements of fractures, overlapping surfaces, foci, etc., which are easily observed in glass and Judea bitumen are also met with in tool steel, as shown in Fig. 8.

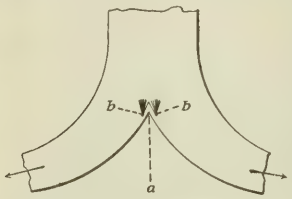

FIG. 11. SCHEME OF TEARING, WITH CRACKS THAT ACCOMPANY IT

We find that the dull part gives the impression that it has been rent or torn away, while the bright surface seems to have been carefully cut. Fig. 10 shows how the dull surface is originated by small rents coming from under the surface. If now we come back to the focus of Figs. 6, 7 and 8, and look for the point where it has been originated, we find that it also lies under the surface.

Fig. 11 shows what takes place in the tearing of a tough substance such as gelatine. The cracking (*bb*) travels ahead of the parting at *a* and prepares the way for its advance.

Fig. 12 is another and striking example of the tearing of a tough material. The parting at the edge of the

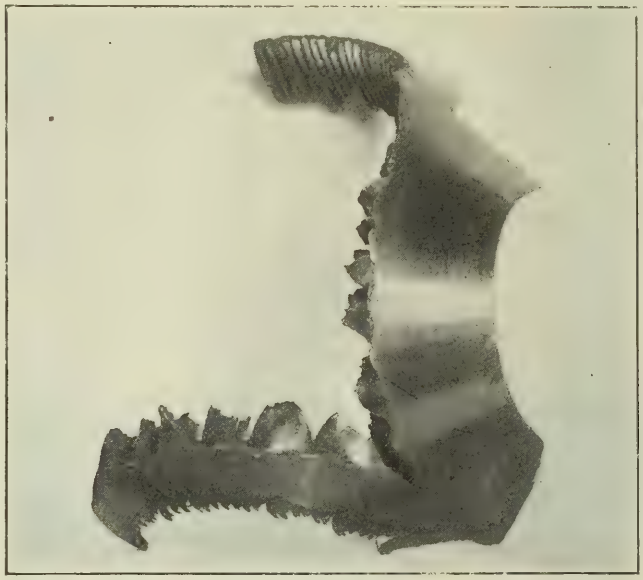

FIG. 12. STEEL CHIP

tool has been made possible by a "cracking" similar to that shown in Fig. 11. The sketch in Fig. 13 shows the scheme of the formation of the steel chip.

But how can a bright surface be produced? How can the cutting process be carried on without the subsurface cracking? How can surfaces be cut which run parallel within such small distance as the ones we have noted? The only explanation which seems to be satisfactory is that the cutting power is a vibratory motion of the surfaces of the fracture, so long as they do not join each other.

Stress and Strain

What are the conclusions to be drawn from this brief presentation of the mechanism of fractures? How can it pretend to be a contribution to the science of resistance of materials? In a general way, by showing the

succession of the phenomena which have taken place during the spreading of the fracture, it affords an experimental proof that the straining effects are more detrimental to the material than mere stress. This is in accordance with what has been shown by a purely mathematical study of the question.

In case of an impact fracture, be it in a piece of glass or in a piece of steel, we find the starting point of the fracture under the surface, although the maximum stress must certainly be located on the surface itself.

In the case of a piece subjected to tension only if a comparison is made with the fractures already considered it will show that fracture has originated along the axis of the test piece. (See Fig. 14.) The surface of the test piece itself sustains a very important stress, but without being subjected to the strains resulting from the contact of layers undergoing uneven stresses, flowing, so to speak, to give the reduction of area.

The predominance of the internal or straining action is no less striking in the case of a rent where the straining effect travels in advance of the stress which could be originated at the separating point. (See Fig. 11.) This condition should induce the metallurgist to pay more attention to the causes which produce straining; in other words, to the tensions which may exist in the pieces after being cast or forged. This is illustrated by the changes in brittleness which occur in glass undergoing heat treatment. The heat treatment does not bring about any change in its molecular arrangement, but the glass coming out of the furnace is very brittle, and after being properly annealed is so much less so that it is in the so-called unbreakable state; that is to say it can sustain shocks and bending to a much greater extent than ordinary glass.

FIG. 13. SCHEME OF STEEL CHIP

The first condition is one of very uneven tension; the second, one without tension; and the third, one which has a beneficial tension. This unevenness of tension also exists in steel, irrespective of the chemical or other changes in structure. An example of the effect of these internal tensions is given by Fig. 15, which shows a fracture in a rail. It is evident that the fracture was started in the neighborhood of the neutral axis, a fact which could not be accounted for if the piece had been under normal conditions; therefore the causes of a fracture of that kind must be traced to a tension most likely produced in the rolling mill. This case illustrates the mode of cutting which produces bright surfaces in glass, and which can only be explained by the presence of a vibratory motion of the surfaces when they are apart from one another.

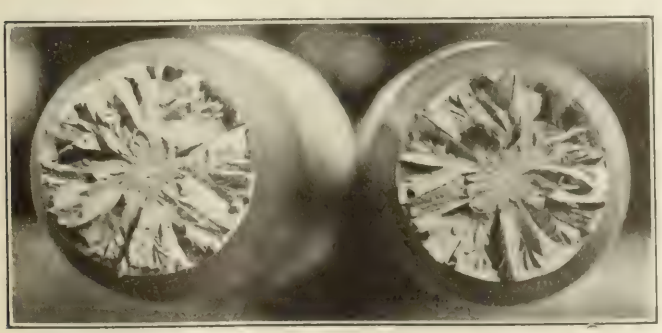

FIG. 14. TEST PIECE RUPTURED UNDER TENSION; FRACTURE ORIGINATED ALONG THE AXIS

FIG. 15. TENSION FRACTURE IN STEEL RAIL

In conclusion, the author trusts he has created the impression that a methodical study of fractures is of the greatest importance, especially as it leads to a knowledge of the causes of failures which cannot always be attributed to the intrinsic qualities of the metal itself.

United States Third in Visible Nitrate Supply

The Association of Producers of Nitrate has made public certain statistics concerning the consumption of this product, according to an Associated Press dispatch.

In the month of February there was on hand in Europe a stock of nitrate of 150,000 tons, and during this same month there was imported into Europe 237,000 tons. Of this total of 387,000 tons there was delivered to the consumer during February a total of 155,000 tons, which left on hand for the month of March a total of 232,000 tons.

The visible supply of nitrate reaches 2,102,000 tons, composed as follows: 1,252,000 from Chile, 492,000 in Europe, 277,000 in the United States and 81,000 in Japan and other countries.

To the 237,000 tons imported by foreign markets during February there should be added 12,500 tons transshipped in the United Kingdom. This gives a total for imports in February of 249,000 tons. The distribution of these imports was as follows: United Kingdom, 11,000; France, 90,000; Belgium, 21,500; Holland, 22,000; Spain and Portugal, 18,000; Italy, 39,000; Scandinavia, 31,000; Egypt, 7,500; Germany and Baltic ports, 9,000.

Production of Sandalwood and Sandalwood Oil in India

A report has been prepared showing the development of the sandalwood oil industry, which is practically a monopoly of the Mysore Government of India, and the distribution of this trade in previous years. The oil is used in the preparation of certain medicines, perfumes and scented soaps.

Australian Flax Industry*

THE Commonwealth Flax Industry Committee, which was established by the Australian Government on the recommendation of the Institute of Science and Industry, has recommended the government to continue the guaranty for raw flax. It is understood that the government does not intend to let this industry languish. Already the area under crop has been increased from 500 to 2,200 acres, and the Flax Committee anticipates that no less than 5,000 acres will be planted during next season.

Before the war Russia produced no less than 80 per cent of the world's output of flax fiber, and when the greater part of the Baltic provinces fell into German hands, as well as the flax-growing districts of Belgium, northern France and the Balkan Peninsula, the shortage of flax fiber among the allied nations for both military and commercial purposes became every day more and more acute. As a result of a meeting of agricultural scientists held in Melbourne in November, 1917, at the suggestion of the advisory council of science and industry a resolution was carried that the advisory council be asked to ascertain whether the British Government was prepared to purchase dewretted flax fiber from Australia in 1919; and, if so, in what quantities and at what price. Inquiries were instituted accordingly, with the result that the army council in England agreed to purchase the fiber from the 1918 flax crop at £170 ($827.30 at normal exchange) per ton c.i.f. The Commonwealth Government thereupon appointed a committee, under the war precautions regulations, for the control and development of the flax industry in Australia, at the same time guaranteeing all growers of fiber flax in 1918 £5 ($24.33) per ton for flax of specified standard.

Previous Efforts to Establish the Industry

For the past twenty years or more fiber flax has been grown on a limited scale in the Gippsland district of Victoria, and attempts have also been made at various times to introduce the cultivation into New South Wales and Tasmania, but without success. Owing to the scarcity and high value of labor and the low price at which flax fiber could be imported, the return the Australian farmer received for his flax did not prove sufficiently attractive to encourage its cultivation, and the few attempts made in recent years to establish the flax industry on a larger scale in Victoria ended so disastrously as to prejudice him still further against this crop. The bounties act, passed by the Commonwealth Government in 1907, provided for the payment of bounty of 10 per cent of the market value of all products from flax grown in Australia, but so little was this inducement availed of that when the act expired, in 1917, not more than 300 acres of flax were under cultivation.

It is more than likely that, in addition to the low returns for fiber and the comparatively high cost of labor, one reason for the retarded development of the flax industry in Australia was the difference in the climatic conditions as compared with those of the fiber-producing lands of Europe, and particularly with those of Ireland, in which country most of the farmers who have attempted flax cultivation in the commonwealth originally gained their experience of this crop. The system adopted in Australia is that of dewretting, the straw being spread over the paddocks in thin layers and the fermentation being brought about by the action of the dew and the sun. Again, in Ireland and in all the European flax-growing countries the custom is to pull the crop by hand, while in Australia it is cut with a reaper and binder. There appears to be no doubt that cutting is wasteful, besides being detrimental to the production of first-quality fiber; but the loss sustained by the Australian grower through the adoption of this method is probably more than compensated for by the greatly decreased cost of labor. Flax growers in Australia had had to learn by the practical experience of local economic and natural conditions, and the methods of cultivation and treatment that have proved successful in Europe may not be equally so in the commonwealth.

Work of the Flax Industry Committee

When the committee was appointed its first act was to requisition all the seed from the previous year's crop. In view of the limited quantity available, the committee decided, as far as growing flax on a commercial scale was concerned, to confine its efforts for 1918 to Gippsland, where it was known that flax could be grown with success, and where one or two flax mills were already in existence. The seed at the committee's disposal was grown in the Drouin district, and was of the variety know as "blue-flowering Riga," the descendant of a small consignment imported some years ago. The quantity available was sufficient to sow only about 1,400 acres, and for a time the advisability of obtaining a further supply from New Zealand was seriously considered. On examination of the samples admitted, however, some doubt arose as to the fiber-producing qualities of the imported seed, and it was decided to utilize only the acclimatized Victorian seed. The wisdom of this determination was proved subsequently by the results of experimental sowings of the New Zealand variety. At Drouin, at the same time and under similar conditions, an acre was sown with the New Zealand seed, and several acres with Victorian-grown seed; but whereas the latter produced one of the best crops in the district, the crop from the imported seed was of so little value as regards both fiber and seed that it was never harvested.

The 1918 Harvest

Owing to the exceptionally dry spring of 1918, the early anticipations of a record harvest were not realized, but nevertheless the average yield of flax was a satisfactory one. Appraisers were appointed at the time of harvesting to inspect and value each crop, and 1,800 tons were delivered for treatment at the various mills. As was inevitable in what was to many growers a new venture, the lack of the necessary experience militated in some cases against the best results being obtained, but the average price paid—£4 15s. ($23.12) per ton—is evidence of the comparatively high standard of the crop. The treatment of the flax at the mills was not completed before the end of 1919, but it was estimated that flax products to the value of approximately £23,000 ($112,000) would be obtained. It is more than likely that, with the experience gained in both the cultivation and treatment of 1918 flax, more profitable results will be obtained from succeeding crops.

*From the *Commonwealth Journal* of the Institute of Science and Industry.

As there was every indication of continued high prices for flax products, the flax committee had no hesitation in recommending the Commonwealth Government to extend the guaranty to the 1919 crop, to place the industry on a surer footing. At the same time, it was thought that, in view of the high returns received by farmers at present for other agricultural products, such as hay, potatoes and butter fat, the guaranty of £5 per ton was hardly sufficient, and an increase to £6 per ton was therefore recommended. The Commonwealth Government adopted the committee's recommendations, and subsequently an agreement was made with the Imperial Government for the purchase by the latter of the 1919 fiber on the same terms as previously given, viz., £170 per ton c.i.f.

The 1919 Crop

The area sown in 1919 was approximately 2,250 acres, an increase of 50 per cent on the acreage of 1918. The cultivation of flax has been introduced into several new localities, 700 acres having been sown in the Sale and Thorpdale districts, while in the western and central districts many farmers are growing this crop for the first time on a commercial scale. Provision will have to be made for the treatment of crops in those districts where milling facilities are not now existent, and the establishment of flax mills on a co-operative basis seems to offer the most satisfactory solution.

While fully assured that the flax industry can be established in the commonwealth on a sound and profitable basis, the flax committee considers that the most effective means of doing so would be a continuance of the present system of commonwealth control. A recommendation, therefore, has been made by the committee to the government that a guaranty of £5 per ton for standard flax be given to growers for a further period of three years, and the matter is now receiving ministerial consideration.

British Plate Glass Industry

Probably none of the war-time industries of Great Britain has shown greater development or more progress than that of glass making. Most of the country's imports of plate glass were from Belgium, but British glass manufacturers are now making a concerted effort to capture this branch of the glass industry from that country. It is estimated that an average of four Belgian ships fully laden with glass of various kinds arrive at the London wharves each week.

In 1914 there were only a few companies in Great Britain making plate glass or optical and chemical glassware. Although several had been established for many years, they were regarded as inefficient and their output was small in comparison with the requirements of the home market. The cutting off of German and Austrian supplies caused a great revival in this industry and many plants were extended on more modern and scientific lines.

English glass makers have been slow to do away with the hand-made method of production, but they realize that if they are to hold the home trade and to eventually successfully compete in foreign markets they must produce on a large scale, which is only possible by the use of machinery.

According to an interview with G. Peters, managing director of the Willesden Glass Works Co. (Ltd.), which was published in the *Daily Express*, his firm has a capacity of 10,000,000 sq.ft. of glass a week and production is at 40 per cent less than Belgian manufacturers. These works were established just before the signing of the armistice, and it is now claimed that it is the second largest sheet-glass factory in Great Britain. The initial cost of the plant was £100,000.

Mr. Peters also said: "There is a world shortage of glass, and we are out to take our share in supplying it. We are following the Belgian hand-blowing system at present, because no machinery has yet been found to give superior results. This, however, is sure to come, and we shall avail ourselves of every development in this direction. Twenty-five per cent of our workers are Belgians. We are training up British workmen for the future by taking on only British boys as apprentices. These boys start right away at 10 pence an hour. Skilled glass blowers can earn from £12 to £16 a week. They are all on piecework and the day is of eight hours."

Quicksilver Produced in 1919

The production of quicksilver in the United States in 1919 was 21,348 flasks, according to F. L. Ransome, of the United States Geological Survey, Department of the Interior. This was a decrease of 11,535 flasks, or about 35 per cent, from the output in 1918. These figures may be slightly revised when the final returns for the whole year are in.

The production by quarters, for 1919, according to the latest revised figures, was as follows:

	Flasks of 75 lb.
First quarter	6,125
Second quarter	4,059
Third quarter	5,413
Fourth quarter	5,751
	21,348

The output for the fourth quarter of the year shows an increase of 338 flasks, or about 6 per cent, over that for the third quarter.

Of the output for the fourth quarter 4,213 flasks were reported from California, 1,032 from Texas, 462 from Nevada, and 44 from Oregon. The proportion for the entire year was: California, 14,941 flasks; Texas, 5,183; Nevada, 821, and Oregon 403. No production was reported from Idaho or Arizona. The number of mines reported as productive during the fourth quarter was eighteen.

The quicksilver reported on hand at the mines or in transit to market at the end of the year amounted to about 4,000 flasks.

The average monthly prices of quicksilver per flask in San Francisco in 1919, as quoted in the *Mining and Scientific Press*, were as follows:

January	$103.75	July	$100.00
February	90.00	August	103.00
March	72.80	September	102.60
April	73.12	October	86.00
May	84.80	November	75.00
June	94.40	December	97.00

These figures give an average price of $90. This price should yield a profit to those operators whose mines are favorably situated and who have ore that averages 8 lb. or more of quicksilver to the ton. It evidently is not enough under present conditions, however, to furnish much incentive to the working of the lower grades of ore to which many of the mines have been reduced, or to encourage very active search for new ore bodies of so capricious a mineral commodity as quicksilver.

Synopsis of Recent Chemical & Metallurgical Literature

Influence of Artificial Carburation of Coal Gas on the Crystallization of Naphthalene in Gas Pipings.—Accumulation of naphthalene in the pipe lines, especially during the cold season, is a very troublesome problem in the gas industry. Cases occur quite often when as much as 1 kg. of naphthalene is deposited per meter of piping (⅔ lb. per ft.).

The methods to separate the naphthalene at the gas plant are based mainly on:

(1) Rapid cooling of the gas leaving the hydraulic main, a method first suggested by Emile Saint-Claire Deville. Thus, when rapidly cooling the gases from its average temperature when leaving the hydraulic main 60 deg. C. (140 deg. F.) to below 20 deg. C. (68 deg. F.) about nine-tenths of the napthalene is condensed with the tar.

(2) By washing the gas after leaving the gas purifiers with heavy oils. This is based on the same mechanical principle as that used to wash the gas with water for the separation of ammonia (method first suggested by Dr. Buels). By this method all the naphthalene contained in the gas can be separated.

After separating naphthalene the candle power of the gas is diminished. This would not be detrimental to the consumer when the gas is used only for heating purposes. When the main use of the gas is for lighting, it is best not to separate the naphthalene, but to hold it therein in gaseous form even at low temperatures. This can be realized by artificially carburating the gas with hydrocarbons derived from oil of coal tar.

CH. AB-DER-HALDEN has made experimental studies on the effect of artificial carburation, and the results of his work are described in the January, 1920, issue of *Chimie et Industrie*. Tables and diagrams are given, which show the influence of the oil used for carburation, and which lead to the following conclusions:

(1) When a coal gas saturated with naphthalene at a given temperature is artificially carburated, it can be cooled below this temperature without the naphthalene solidifying, as it is retained in the form of a gaseous solution by the carburating vapors.

(2) The efficiency of the treatment depends on the boiling point of the carburating agent and not on its chemical composition, and the best results are obtained with oils boiling between 80 and 90 deg. C.

(3) The cooling point of the treated gas up to which the napthalene will not solidify out depends on the quantity of the carburating agent used.

(4) The influence of carburating coal gas supersaturated in naphthalene is the more marked the greater the contents of the naphthalene in the original gas.

Some Properties of Sodium Nitrite.—Sodium nitrite plays an important role in the synthetic manufacture of HNO_3. C. MATIGNON and Miss C. MARCHAL have studied some of its properties. (*Comptes Rendus*, vol. 170, No. 4, pp. 232-233.) They worked on a very pure product, analyzing 99.9 per cent $NaNO_2$ and have found the following results:

Fusion point, 276 deg. C.

Heat of Solution. Sodium nitrite dissolves with comparative ease, the molecular heat of solution is —3.52 cal. at 20 deg. C.

Heat of Neutralization. This has been determined by adding a calculated quantity of sulphuric acid to a dilute solution of the nitrite, and was found to be 4.6 calories on the average.

Heat of Formation. The above values added to the heat of formation of the nitrous acid as determined by Berthelot:

$$N + O_2 + H + aq = HNO_2 \text{ solution} + 30.3 \text{ cal.}$$

and to the thermal constants of soda and sodium oxide give for the heat of formation of the solid nitrite 88.52 cal.

$$N \text{ gas} + O_2 \text{ gas} + Na \text{ solid} = NaNO_2 \text{ solid} + 88.52 \text{ cal.}$$

Action on Colored Reagents. The action of nitrous and nitric acid with phenolphthalein, cochineal, lacmoid, paranitrophenol, brazilian and iodeosine is the same. Helianthine is destroyed by nitrous acid.

Action of Oxygen. Sodium nitrite solution cannot be oxidized directly, even when maintaining the solution at 100 deg. C. in contact with oxygen under a pressure of 50 and 55 atm. for 5 to 6 hr. and with continuous agitation. The same negative results were obtained by the use of an oxidizing catalyzer, such as platinum black.

Comparative Study of Electrically and Coke Heated Blast Furnaces.—The relative expenditures of heat and the compositions of gases obtained in electrically and coke heated blast furnaces have been studied by MARCEL GUÉDRAS and described in the Jan. 20, 1920, issue of *Revue de Métallurgie*. Tables I and II give respectively the data of the heat expenditure in an electric furnace at Trolhättan, Sweden, and in a 90-ton furnace using coke.

TABLE I. HEAT SPENT IN AN ELECTRICALLY HEATED BLAST FURNACE PER METRIC TON OF PIG IRON

	Calories.
Reduction of 91.02 kg. Fe from Fe_2O_3	163,836
Reduction of 873.118 kg. Fe from Fe_3O_4	1,440,648
Reduction of 3.110 kg. Fe from FeO	725
Reduction of 0.160 kg. Mn from Mn_3O_4	315
Reduction of 4.270 kg. Mn from MnO	7,387
Reduction of 3.420 kg. Si from SiO_2	26,779
Reduction of 0.186 kg. P from P_2O_5	1,096
Heat of fusion of iron and slag	402,400
Heat of decomposition of carbonates	49,134
Heat of vaporization of 87.38 kg. H_2O, less cooling to 60 deg. C.	53,479
Tensile heat of dry gases from 10 to 60 deg. C.	
128.01 kg. CO_2 ... 1,280	
591.36 kg. CO ... 7,229	
10.54 kg. CH_4 ... 314	
3.73 kg. H ... 640	
	9,463
Total	2,155,262

TABLE II. HEAT SPENT IN A COKE-HEATED BLAST FURNACE PER METRIC TON OF PIG IRON

	Calories
Reduction of 950 kg. Fe from Fe_2O_3	1,792,650
Reduction of 10 kg. Si from SiO_2	78,300
Fusion of 1000 kg. pig iron	300,000
Fusion of 1452 kg. slag	726,000
Decomposition of 1,170 kg. carbonates	438,750
Vaporization and heating to 250 deg. C. of 96 kg. H_2O	74,736
Decomposition of H_2O contained in the air used	19,320
Heat entrained by the gases	47,374
Losses	450,000
Total	3,927,130

In the electrically heated furnace the quantity of heat furnished per metric ton of pig iron is 2,155,262 calories, of which 908,830 calories are obtained by burning 34.91 kg. C to CO_2 and 113.44 kg. C to CO, leaving a balance of 1,246,432 calories to be supplied by electric

energy, corresponding to 1,454 kw.-hr. In the blast furnace 1,100 kg. of coke is required per metric ton of pig iron. The tables show that the heat spent in the blast furnace is 1,771,863 calories more than in the electric furnace. Improvements in the electric furnace construction and operation will certainly increase this marked difference.

The composition of the gases from the blast furnaces is:

	Blast Furnace Per cent	Electric Furnace Per Cent
CO_2	18.60	14.12
CO	22.15	83.00
CH_4	0.62	0.54
H	0.08	1.86
N	58.55	0.48

Their calorific heat is, in blast furnace, 638 calories; in the electric furnace, 2,257 calories. The amount of gas produced per ton of pig iron is, in the blast furnace, 5,615 kg.; in the electric furnace, 737.9 kg.

Expressed in calories the total heat values of the gases in the two types of furnace are respectively 3,582,370 and 1,665,485 calories. This shows an apparent advantage for the blast furnace, but as a matter of fact the electric furnace gas is superior and more useful than that from the ordinary blast furnace.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Halogen Substitution Products. — Oxidation and reduction reactions in the gaseous phase, such as the substitution of a halogen in gaseous carbon compounds, may be carried out in an apparatus devised by WILLIAM KOEHLER of Cleveland, Ohio. The gases are passed separately through nozzles so arranged that the streams of gas converge at a point beyond the nozzles. Thorough mixing results and an electric spark or arc is provided at this point so that mixing and heating to the reaction temperature are accomplished simultaneously, thereby preventing premature explosions of the mixture. (1,332,730; March 2, 1920.)

Nitric Acid.—A mixture of niter cake and sodium nitrate is passed through an inclined rotating kiln which is heated in a furnace in such a manner that the lower portion of the retort is subjected to the highest temperature. A sharp-edged iron bar is placed lengthwise in the retort, so that it tumbles about as the retort revolves and prevents the mass from adhering to the sides. A slow current of air through the apparatus effects the oxidation of the lower oxides of nitrogen and maintains the flow of the gases through the condensers and absorbers. (1,332,195; THOMAS F. BANIGAN of Kenvil, N. J., assignor to Hercules Powder Co., March 2, 1920.)

Naphthalene-β-Sulphonic Acid.—Sulphuric acid of 75 per cent strength is preferable to concentrated or fuming acid for the production of naphthalene-β-sulphonic acid. When sulphonation is carried on with this acid at about 160 deg. C. for a period of from 1 to 1¾ hr., the product contains only 22½ to 26 per cent of the α-sulphonic acid and very small amounts of sulphones, disulphonic acids and gum-like insoluble carbonaceous residue. The β-acid is preferably extracted from the mass by the use of toluene according to the method described in U. S. patent 1,228,414 of June 5, 1917, also granted to the present inventor, LOUIS M. DENNIS of Ithaca, N. Y. (1,332,203; March 2, 1920.)

Copper-Lead Smelting Process.—Methods by which complex ores carrying copper, lead and zinc can be economically treated for the recovery of the metals are of particular interest at the present time. As a general proposition, coke is expensive at mining centers, whereas soft coal may be relatively cheap and electric energy is usually available at a reasonable price.

WOOLSEY MCA. JOHNSON, of Hartford, Conn., proposes to take advantage of these general facts in a process for the recovery of copper, lead and zinc. The basic and acidic components of the charge to be smelted are heated separately in rotary kilns, using coal or coal dust for fuel. These are fed separately to an electric furnace in which the reduction takes place in such proportion that a slag of approximately the following analysis will result: SiO_2, 40 per cent; CaO, 20 per cent; FeO, 30 per cent, and ZnO, 10 per cent. In this operation lead bullion and copper matte will be produced in the same manner as in a lead blast furnace. The slag and matte are passed through two electrically heated settling hearths. In the first settler matte will be tapped out at intervals, while the slag, partly freed from matte, will pass to the second settler, where some fine carbonaceous material will be added to reduce the ZnO, and any dissolved PbO or CuO. In case much lead is present and in case an extremely high temperature is used, it is necessary to collect the lead fume from the electric furnace in a suitable apparatus. Also, in cases where no lead is present in the ore, the ratio of CuO to Cu_2S is so proportioned that the reaction $2CuO + Cu_2S = 4Cu + SO_2$ takes place, producing copper bullion directly from the ore.

It is evident that by this process but small amounts of electricity are used and that it plays a rôle similar to that of small amounts of coke in pyritic smelting. By employing indirect methods of heating, fine ore or flotation concentrates can be smelted without dusting. A representative slag will contain, it is claimed, less than 0.1 per cent of copper and lead, and not more than half an ounce of silver with no gold. If proper precautions are taken the electrode consumption is not over 4 lb. per ton of ore treated. (1,333,720; March 16, 1920.)

Electric Furnace.—A patent covering the design of a revolvable electric furnace has been granted to WILLIAM K. BOOT. This furnace was described in CHEMICAL & METALLURGICAL ENGINEERING, vol. 21, p. 636, Nov. 12-19, 1919. (1,332,795; March 21, 1920; assigned to the Booth Electric Furnace Co., of Chicago, Ill.)

Recovery of Copper From Its Ores and Solutions.—H. LIVINGSTONE SULMAN and H. F. K. PICARD, of London, England, have been granted a patent on the above subject which is assigned to Minerals Separation, Ltd. One object of the invention is to precipitate copper from copper solutions obtained in metallurgical operations in an effective and economical manner, in the form of sulphide; a further object is to utilize this precipitation for improving the recovery of copper from its ores by the froth-flotation process of concentration as described, for example in U. S. Pats. 835,120, 962,678 and 1,064,723. The method consists in adding a precipitant containing ferrous and calcium sulphide to the copper-bearing solution and separating the copper

sulphide precipitated. The precipitant is produced by heating pyrites, or chalcopyrite, bornite, etc., with an equivalent of lime to a low red heat and cooling out of contact with air. (U. S. Pat. 1,178,191.) The effective use of this precipitant requires the presence of a definite quantity of sulphuric acid in the solution and a certain time factor for efficient use. Both the copper sulphide and any copper in the pulp will be floated. (1,333,688; March 16, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Cellulose Ester Solutions.—The viscosity of solutions of nitrocellulose, acetylcellulose, celluloid and other cellulose esters is permanently reduced by heating the solutions, meanwhile preventing the escape of solvent, to a temperature between 60 deg. C. and the temperature at which the ester in question is decomposed. The temperature and duration of the heat are correlated; the longer the heating and the higher the temperature the more is the viscosity reduced. (Br. Pat. 136,141—1919; O. CARLSSON and E. THALL, Stockholm, Feb. 4, 1920.)

Toluene Sulphochlorides. — Toluene-o-sulphochloride is separated from mixtures with its paraisomer containing 60 to 70 per cent of the ortho compound by seeding the liquid mixture at about —6 deg. C. with a crystal of the ortho compound and removing the crystalline ortho compound which separates out. The initial mixture may be obtained by treating toluene with chlorsulphonic acid and crystallizing out a portion of the para compound at —20 deg. C. (Br. Pat. 135,987—1919; F. E. MATTHEWS and E. H. STRANGE, London, Feb. 4, 1920.)

Lactose.—In obtaining lactose from whey, the albumen is precipitated by metaphosphoric acid. The whey is concentrated in vacuo to about one-fifth of its bulk and then heated to about 70 deg. C. A portion of the albumen is thus coagulated and is removed by skimming or decantation. The metaphosphoric acid is then added and the resulting precipitate removed by filtration or settling. The lactose is then obtained from the clear liquid by crystallization in the usual way. (Br. Pat. 135,614—1919; G. MARTIN, Manchester, Jan. 28, 1920). The albumen may also be precipitated by tannic acid, mercurous nitrate, phosphotungstic acid or magnesium sulphate. (135,969—1919. Feb. 4, 1920.)

Phenol Aldehyde Condensation Products.—In the production of insoluble condensation products from phenol or its homologues and formaldehyde or its polymers in the presence of an alkaline accelerator, from 6 to 20 per cent of a vegetable fatty oil (castor, linseed, rape, cottonseed, etc.), or camphor oil is added, either to the initial mixture or after the first stage of the reaction; the product is finally hardened. The product so obtained is flexible when hot. (Br. Pat. 136,298—1919; F. J. ROBINSON, Cowley, Middlesex, and DAMARD LACQUER CO., Westminster, Feb. 4, 1920.)

Purifying Mineral Oils.—In the purification of mineral oils by sulphuric acid and alkalis powdered anhydrous alkali carbonate is used, preferably with calcium chloride or other drying agent, to give a perfectly dry oil. In an example, acid-treated oil, washed with hot water if it is desired to recover the sulphonic and naphthenic acids, is decanted into a vat, heated to 58-70 deg. C. and agitated, while dry anhydrous sodium or potassium carbonate or ammonium carbonate or bicarbonate is strewn over the surface along with calcium chloride. The alkali sulphate, calcium chloride and excess of carbonate are allowed to settle and the oil then filtered. (Br. Pat. 136,169—1919; G. GRISARD, Basel, Switzerland, Feb. 4, 1920.)

Production of Ammonium Nitrate. — Ammonium nitrate is produced in the solid form by bringing together oxides of nitrogen, oxygen, water and ammonia under such conditions that the proportion of oxygen present is in excess of that required to convert the whole of the oxides of nitrogen into nitrogen dioxide, the proportion of ammonia is insufficient to react with the whole of the oxides or nitrogen, and the proportion of water is not in excess of, and is preferably equal to, that which is sufficient to convert the whole of the ammonia added into ammonium nitrate by interaction with the oxides of nitrogen and oxygen. In the case of gases containing about 10 per cent by volume of oxides of nitrogen, produced, for example, by the oxidation of ammonia, an amount of oxygen equivalent to three or four times that theoretically required to convert the whole of the oxides of nitrogen into nitrogen dioxide may be added. The oxygen may be added in the form of oxygen gas, air, or air enriched with oxygen, and the water should be in a finely divided state, for example as vapor or spray. (Br. Pat. 136,190—1919; J. R. PARTINGTON, of the Munitions Inventions Research Laboratory, University College, London, Feb. 4, 1920.)

Concentrating Ores. — The product obtained by treating a soluble soap or its ingredients such as sodium oleate with sulphur, or by treating a fatty acid with a soluble alkaline sulphide, or by adding a soluble soap to an aqueous solution of sulphuretted hydrogen, is used as the mineral-frothing agent in froth-flotation processes. The agent may be obtained by heating the soluble soap or fatty acid with the sulphur or sulphur-containing material, and may be used in processes of differential separation or in the concentration of sulphide or oxidized ores. In some cases acid may be added. (Br. Pat. 136,255—1919; S. TUCKER, E. EDSER and MINERALS SEPARATION, LTD., London, Feb. 4, 1920.)

Treating Ores. — Ores containing more than one sulphide are treated with a solution of a chloride (ferric chloride and manganese chloride being mentioned) which exercise a selective action leaving one or more sulphides, such as zinc sulphide undissolved, and dissolving other sulphides to form chlorides, such as lead, copper, silver and gold chlorides, with precipitation of sulphur. This precipitated sulphur may be separated from the undissolved matter by flotation, or may be left with the zinc sulphide, as it facilitates the roasting of this body and yields a gas richer in sulphur dioxide and suitable for the production of sulphuric acid. The metals contained in the solution may be separated in known manner; for instance, lead may be precipitated by iron, or electrolysis may be employed, or the chlorides may be crystallized. The ferrous chloride resulting from the process may be reconverted into ferric chloride by treatment with chlorine or with air in the presence of hydrochloric acid, or by evaporation to dryness and calcination, in which case ferric chloride sublimes, leaving a residue of ferric oxide. (Br. Pat. 136,163—1919; SOC. ANON. MINERAIS ET MÉTAUX, Paris, Feb. 4, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Republican vs. Democrat on the Nitrate Program

FURTHER expenditure of funds by the War Department on the Muscle Shoals Nitrate Plant should be discontinued, in the opinion of the majority of members of the select committee of the House of Representatives, which has been investigating the matter. However, the minority is unable to agree on this point; in fact the committee is hardly able to agree among themselves on any point. For instance, the majority damns the Air Nitrates Corporation, while the minority as stoutly upholds the Air Nitrate Co.—presumably the same organization! Briefly, the majority condemns the nitrate program as a waste of effort directed by B. M. Baruch at the instigation of Washburn, Worthington, et al., who were to profit from it. They also contend that Chilean nitrate should have been relied upon to make up any deficiency from coke ovens; that the plants were improperly located, extravagantly built, following processes which would either not work or should be promoted by private enterprise. Opponents to the Government program were disciplined during the war, and now the Ordnance officers who directed the construction are held up for severe censure. Muscle Shools, if operated, should produce fertilizer nitrogen, yet the men in charge are held culpable for completing the work, acquiring operating power and a lime quarry. In general, it was a sad débâcle and should be abandoned immediately! Reverse all these ideas, and the reader has the minority view.

The committee agrees that Plants 3 and 4 should be salvaged, that the Alabama Power Co. took unfair advantage of the Government's need of power, and that the Wilson Dam will require $12,000,000 for completion.

As to the disposition of the Muscle Shoals plant, the minority holds that this is covered by a pending bill in Congress and declines to discuss the majority recommendation that it be leased under restrictions for private operation.

Program's Contribution to Victory

1. The majority finds that there has been expended for construction upon the Government's nitrate program to the present time the sum of $116,194,974.37, and that this expenditure produced no nitrates prior to the armistice, and contributed nothing toward the winning of the war.

The minority grants that no nitrates were produced at these plants prior to the armistice, but utterly disagrees with the statement that the expenditures contributed nothing to the winning of the war. If the expenditures for the war program are to be criticized, or their necessity or non-necessity judged because hostilities came to an end unexpectedly in November, 1918, then probably three-fourths of the nation's efforts were useless.

Activities of Baruch

2. According to the majority, the nitrates program originated with the War Industries Board of the Council of National Defense, and is directly traceable to Bernard M. Baruch, chairman of that board.

On the other hand, the Democratic view holds that the nitrate program grew out of the necessities determined by the Gun Division to be essential according to the number of divisions which the General Staff planned from time to time to put into the field. Mr. Baruch played a most important and highly praiseworthy part.

Was Nitrate Program a Misdirected Effort?

3, 4, and 5. The Republicans hold that had the labor and money required to construct the nitrate plants been utilized in producing food or other war essentials, real assistance would have been rendered in winning the war. In June, 1916, Congress appropriated $20,000,000 for the manufacture of nitrates, then the policy of neglect, delay and do-nothing was followed in that regard by the President and the War Department until the late fall of 1917. Had the War Department, early in 1916, purchased and stored in this country large quantities of Chilean nitrates as was advised by General Crozier to the Secretary of War, the only excuses for the building of Government nitrate plants in the late fall of 1917 would be lacking.

The minority charges inconsistency in these three allegations, which are said to be the fundamental principles of the majority report. In substance, paragraph 5 criticizes the President of the United States for not, while we were at peace, hastily embarking upon a war-supply program, which paragraph 4 declares was, when embarked upon after we had gone into the war, "one of misdirected effort," and for which paragraph 6 declares there "was no national necessity at any time." Chilean nitrates could not be purchased on account of lack of funds, and its storage would have embarrassed the explosives program of England and France. The majority omits to state that at the very same time, in 1915 in fact, General Crozier was investigating the subject of nitrogen fixation and recommended the development by the Government of such processes along with the purchase of Chilean nitrates.

Possible Reliance on Chilean Nitrate

7, 8, and 9. These findings contain allegations by the majority that submarine menace and probable high price were not valid reasons for abandoning reliance on Chilean nitrate which, barring coke-oven nitrogen, comprised our entire supply and was able to build up a reserve of 600,000 tons despite our war requirements.

The minority contends that the submarine was a real danger to our supply, and cites the following additional reasons for an internal supply: (*a*) Shortage of ships. (*b*) Need of ammonia as distinguished from sodium nitrate. (*c*) Large but unknown naval requirements. (*d*) Requirements of Allies. (*e*) The propellent requirements as distinguished from explosives. These consisted largely of smokeless powder, for the production of which immense quantities of nitrogen must be had. (*f*) Cumulative demand for nitrogenous fertilizer. As a matter of fact the 600,000 tons was less than two months' supply at the then rate of manufacture.

10. The whole committee reaches approximate agreement that as a result the United States has the following nitrate plants finished or partially finished:

(*a*) Experimental Nitrate Plant No. 1, at Sheffield, Ala., constructed for the manufacture of nitrates by the General Chemical Co. process, at a cost of $12,152,636.91, which plant is supposed to be completed. As pointed out in the minority report, the nitrate feature of Plant No. 1 at Sheffield constituted but one of its units, and it is the only unsuccessful part. This unit was to produce ammonia. It cost $5,502,170.13, including its proportion of overhead expense.

(*b*) Plant No. 3, partially constructed plant at Toledo, Ohio, which cost $7,781,609.06.

(*c*) Plant No. 4, near Cincinnati, Ohio, partially constructed, at a cost of $7,578,229.84.

(*d*) Plant No. 2, at Muscle Shoals, Ala., completely constructed for the manufacture of nitrates by the cyanamide process, at a cost of $69,985,221.42.

(*e*) In addition to the foregoing, the Government has made an expenditure of $5,167,277.42 upon the property of the Alabama Power Co.

(*f*) A quarry site in northern Alabama which cost $60,000.

(*g*) An unfinished dam on the Tennessee River at Muscle

Shoals, Ala., for which there has been allocated $13,170,000, and which, to complete, will require approximately an additional $12,000,000, but according to Democratic view, the dam has only the remotest connection with the nitrates program.

Location of Plants

11. Blaming the President for ill-advised choice in location of the plants, and particularly for ordering the Wilson Dam at a time when he must have known it could not be completed with the funds available for that purpose, and that it could not be completed in time to be of service during the war, the majority view, is countered by the minority's statement that the President and the Secretary of War, either together or singly, may safely assume this responsibility without apology and without it adding to their burdens. They also call attention to the fact that the Wilson Dam was not a war project, in the sense that it had any bearing upon or connection with the war with Germany.

Opponents to Program Disciplined

12. In the words of the minority, the majority's assertion that anyone who opposed or sought to modify the plans of the President and Secretary of War for the development of Muscle Shoals was either disregarded or disciplined is wholly gratuitous. Colonel Hugh Cooper's recommendations as to the Muscle Shoals dam were largely carried out, and a transfer to be Base Engineer at Bordeaux could hardly be regarded as a demotion. No hint was heard that Dr. Charles L. Parsons was disciplined for his opposition to the location of Plant No. 2. His advice upon matters was freely given before and after that time, sometimes acted upon and sometimes not.

It was partly upon Dr. Parsons' recommendation that the Experimental Plant No. 1 (General Chemical Co.'s process) was established, the plant which failed to function. He is a believer in the future great possibilities of the pressure process in competition with other processes and is, as he frankly told the committee, personally interested now in a business way in its development. He was not so interested at the time of his recommendation. We do not deem it any reflection upon Dr. Parsons that the Experimental Plant No. 1 has not yet in its ammonia unit been successfully operated. He had data sufficient to justify the recommendation and the authorities were justified in following it.

Blundering Trial of Haber Process

13. The majority refers to the expenses incurred at Plant No. 1 (modified Haber process) as a colossal blunder and waste of public funds. While the minority admits that too expensive construction was provided, especially in living quarters, they feel that a venture with a process which gave Germany one-third her nitrates during the war was well advised. The General Chemical Co. had carried on laboratory experiments which had been sufficiently satisfactory as to cause it to determine to go into the business commercially, and it was preparing to expend an immense sum of money in the construction of a plant, and had expended about $500,000 assembling materials when the Government became interested. The enterprise was undertaken, admittedly as an experiment, upon the recommendation of eminent scientists, including Dr. Charles L. Parsons, of the Bureau of Mines, who had made exhaustive studies of the various methods in use in the European countries for nitrogen fixation.

Influence of Washburn and Worthington

14, 15, and 16. The minority declares to be wholly misleading the majority's finding that the building of Plant No. 2 at Muscle Shoals was the deciding factor inducing the building of the Wilson Dam—a culmination of years of effort and striving of Washburn, Worthington and others to induce the National Government to dam the Tennessee River for the production of hydro-electric power at Muscle Shoals, a hydro-electric development redounding to the profit of various interests of these two men.

Colonel Joyes Upheld by Minority

17 and 18. The two contracts made by the War Department with the Air Nitrates Corporation, the first being dated Nov. 16, 1917, and the second June 8, 1918, are unilateral and unfair and unjust to the Government. The Ordnance officers, charged with responsibility, failed in most instances to guard the interests of the United States in the contracts for the construction of the nitrate plants. In particular, Colonel J. W. Joyes deserves severe censure for signing the second contract, for purchasing chemical equipment for twice its market value, and his zeal in carrying out the agreed program after the armistice had been signed.

On the other hand, the minority states that it is not correct that the Ordnance officers charged with responsibility failed in most instances to guard the interests of the United States in the contracts for the construction of the nitrate plant and they repudiate emphatically the assertion that Colonel J. W. Joyes merits censure. This faithful officer of the Regular Army, denied the opportunity of serving on the battle line because he was needed here, has rendered to his country, in a position of gravest responsibility behind the lines, a service which entitles him to the praise and honor of his countrymen. Working under the most extreme difficulties, having upon him a very large degree of responsibility for furnishing the munitions upon which success depended, he has acted upon principles of the highest integrity and with commendable prudence. He was not satisfied with the terms of all the contracts which he was compelled by circumstances to enter into. It was a matter of bargaining for things which the Government absolutely had to have and which those with whom he was dealing knew it had to have. That he succeeded, as the record shows he did, in again and again securing modifications of proposals, every such modification being in the interest of the Government, at a time when the cry from everywhere was "speed" and "still more speed," and those with whom he was dealing knew it and knew that they held practically both ends of the string, does greatest credit to his industry, his powers of persuasion, and his patriotism.

Misuse of Appropriations

20. In the opinion of the majority, the funds used to construct Nitrate Plants 2, 3 and 4 were taken from the said "Armament of fortifications (C)" fund, not contemplated by Congress to be used for such purposes.

The minority appear surprised at this statement and understand the assertion to be merely the opinion as to the ignorance of Congress. The terminology "Armament of fortifications (C)," which has been carried in the fortification appropriation bills for long years, they thought had been thoroughly understood by members of Congress, at least. It is the item from which funds have been all along derived by Ordnance for its needed munitions and all the processes essential to obtain them, except a certain amount carried in the fortifications bill under the terminology, "Practice and field artillery ammunition."

Collusion at Muscle Shoals

21. It is obvious to the majority that the War Department forced the completion of this work after necessity had vanished. When hostilities had ceased, an uncompleted steam power plant costing $10,000,000 was rushed to completion; the Waco quarry has been acquired and $60,000 has been expended for land for the same; a modern electric plant, industrial village, transmission lines, and railroads have been completed for the Alabama Power Co. at a cost of over $5,000,000, while work on the Wilson Dam, which had been suspended by the Priorities Board, when it was known an armistice would be signed, on Nov. 9, 1918, was ordered recommenced and rushed.

In the minority view it appeared natural that the War Department was intensely interested in having this magnificent plant 100 per cent complete, because it is without a doubt the nation's greatest material military asset. The manufacturing part of this plant, having a capacity of 110,000 tons per annum of ammonium nitrate, was completed to the point where it was ready to be put into successful operation. The steam-power plant had reached a stage of completion that made it wise business economy to finish it, rather than to leave it standing as a useless ruin; practically all of the machinery had been ordered and commitments were outstanding. As to the other matters, the Government carried out its pre-existing contracts. As for the dam, let it be clearly understood that the President of the United States directed this dam to be built in accordance with the duty imposed upon him by the national defense act of 1916. That dam is for peace uses as well as war uses. It is expressly so stated in the law itself and was so interpreted in practically every argument made upon it in the House and Senate by friend or foe while the legislation was being considered. The hydro-electric power to be there created is to be used by the very terms of the law itself for the making of fertilizer in times of peace and munitions in times of war.

Location of Plants Nos. 3 and 4

22 and 23. The majority holds that the location of Plant No. 3, at Toledo, Ohio, was entirely unsuitable for such a plant, it being surrounded by water and otherwise largely inaccessible. The site selected for Nitrate Plant No. 4, in the Little Miami Valley, near Cincinnati, Ohio, was equally unsuitable, in a locality where construction was costly, labor hard to accommodate, and with high prospective expense for transportation of raw materials. It seems that

they were located in Ohio because a Congressman needed to distribute a certain amount of pork.

However, the minority again finds itself unable to agree with the majority. After some remarks about 1861, it states, so far as the record is concerned, the controlling element in locating Plant 3 at Toledo and Plant 4 at Cincinnati was the fact that there was available at these two cities, and could be secured from facilities already in existence, large blocks of power not elsewhere procurable and absolutely indispensable, a question of very great importance in the war activities.

In justice to the Ohio Member of Congress who has criticized the construction of Plant No. 2, it should be said that his criticism was not leveled at the place—Muscle Shoals—but at the construction of a plant for nitrogen fixation by the cyanamide method anywhere, he, like Dr. Parsons, being a believer in the Haber plan or in one of its modifications.

Was Construction Wasteful and Poorly Executed?

24, 25 and 26. The cost-plus system adopted by the Ordnance Department is, in the majority's view, unduly expensive and demoralized the country's labor. Waste of labor and material was rampant which under ordinary circumstances would approach criminality. Particularly the Air Nitrates Corporation was extremely faulty and inefficient in organization and experience.

In view of the necessity of haste, the impossibility of preparing final and complete plans, and the general instability of materials and labor markets, the minority contend that the cost-plus system was the only practicable method of construction. Some leading contracting firms, whose integrity is above all suspicion, use it almost exclusively, and have for years. The sworn testimony of responsible officials of the Air Nitrates Corporation is to the effect that the costs of labor and materials upon the whole job were in the ratio of 34 per cent to 66 per cent—that is, 34 per cent of the total cost was for labor and 66 per cent for material. It is understood that the usual proportion is 40 per cent to 60 per cent. It is further testified to that there has been an inventory taken with the most painstaking care of every item in every structure and this checked with the invoices paid, with the result that there is shown a deficiency or loss of material of 1.61 per cent.

Air Nitrates Entered Into a Trust Relationship

27. Both parties agree to this item, the minority, however, disclaiming the inference that the principle has been violated. By the contracts between the Air Nitrates Corporation and the United States the Air Nitrates Corporation became the agent of the United States, and hence the relation between that company and the Government was of a fiduciary character, a trust relation which required the utmost good faith and reasonable diligence in protecting the interests of the Government from the destruction and waste of its property by its employees and subcontractors. Complete settlement has not been made with the Air Nitrates Corporation by the Government on account of these contracts.

Shall the Government Operate Muscle Shoals?

28 to 37. The majority believes that it is for the best interests of the country and for the public welfare that there be built up in the United States a nitrate industry by private initiative and capital, capable of supplying the wants of our people for fertilizers in times of peace and explosives in times of war. If a governmental agency should engage in the commercial manufacture of nitrogen compounds for sale, it would discourage and retard this development. Consequently it would be unwise for it to build and operate a plant in conjunction with Nitrate Plant No. 2, at Muscle Shoals, for the manufacture of ammonium sulphate and other nitrogenous compounds for commercial purposes. Furthermore, the disposition of such byproducts as lime and crushed rock would destroy private business in these lines within a radius of 200 miles. However, if Muscle Shoals plant should be operated at a low cost and produce annually 86,000 tons of ammonium sulphate, such amount would be so inconsiderable, in comparison with the total amount required in the United States for all purposes as to make little or no appreciable reduction in the price of agricultural fertilizers. Still, even this amount would not be salable since the quantity produced by the byproduct coke ovens is largely in excess of any amount of ammonium sulphate ever used heretofore in the United States for agricultural purposes. There are 11,000 of these ovens now in operation, 1,500 of which were constructed by Government funds, and the majority is loath to prevent further conservation of natural resources by the supplanting of beehive by retort ovens by appearing to compete with them for the ammonia market. Notwithstanding the fact that the majority calls a governmental experiment in the Haber process a blunder, it understands that private enterprise is now formulating plans for the commercial manufacture of fixed atmospheric nitrogen by the Haber process. They admit for their present argument that it is generally known that the Haber process is much more economical and efficient in operation than the process now used at the Muscle Shoals plant, and that every reasonable encouragement should be given private enterprise. Private enterprise would hesitate and in all probability cease its intention of entering into a business in which any agency of the Government was to compete with products from a plant or possibly a chain of future plants built by Government funds and maintained by the National Treasury and not subject to limitations of the national defense act. On account of the character of Nitrate Plant No. 2 at Muscle Shoals, if it was salvaged the Government would hardly be recompensed for the expense of salvaging it. Three feasible plans for the future of this plant are presented: First, that the plant be kept in a standby condition; second, that it be leased to and operated by private enterprise, with such reservations in the lease as shall reserve to the Government the right to use it in the event of war with reasonable reservations as to price regulation by the Government, and with the further reservation that the product be offered in the general market so that it can be purchased direct by the consumer, including the farmers of the United States, and the majority finds that such a lease can be made; third, that it be operated by the Government.

All these questions the minority dodges on the basis that it is an adverse report upon a legislative proposal now pending, not before the select committee but before the Committee on Military Affairs of the House, to wit, a proposition to install at Nitrate Plant No. 2 the necessary equipment to extend a portion of its units so that ammonia sulphate, which is a desirable form of ammonia for fertilizer purposes, can be produced, and to organize a Government-owned corporation to operate it and sell this product into commerce.

Abandonment of Plants 3 and 4

38. Here the committee seems to be as a unit that these plants should be salvaged as soon as possible, and proper settlements made of all claimants without protracted delay.

Equipment of Waco Quarry

39. The minority, on the same grounds as cited in 28-37 above, declines to discuss the recommendation that it would be unwise for the War Department to attempt to develop the so-called Waco quarry, and that no further expenditures should be made until some policy as to the future of the Muscle Shoals plant shall have been adopted by Congress.

Contract With Alabama Power Co.

40. An expenditure of over $5,000,000 for development of the property of Alabama Power Co., in the opinion of the majority, was unjustifiable and unnecessary, and the same results might have been accomplished by a loan of less than half this amount. The result of this expenditure has been to build up the property of a private corporation and establish it as a power monopoly in northwestern Alabama.

This contract is not upheld by the minority. So far as the record goes the Alabama Power Co. does not stand in a favorable light therein. The conclusion cannot be escaped in the light of testimony that at some stages of the proceeding the company appeared to have imposed upon the Government's necessities and unduly forced increases in certain of its facilities. The contract with this company and various things done in its execution were not satisfactory to the contracting officer in all their phases. It was simply a case where he did the best he could. The pressure was insistent, growing out of public necessity for getting the plant into operation, to begin producing explosive material for the expected 1919 military campaign. The steam power plant could not be gotten ready in time to coincide with the manufacturing part of the enterprise, nor could the dam at Muscle Shoals. At the time the first proposition of this company was submitted to Colonel Joyes, suggesting a Government loan to it of $2,250,000, there was no authority of law to make loans to private industry. The statement is incorrect, that the same results "could have been attained by a Government loan of half the amount."

Wilson Dam Requires 12 Millions More

41. The whole committee finds that the Muscle Shoals Dam, without the building of at least two other dams, will not improve the navigability of the Tennessee River. That to complete the Muscle Shoals Dam will require an additional appropriation of approximately $12,000,000.

The bulk of the majority's report thus appears to be a criticism of the nitrate program, a plan of action formulated under great stress of urgency and in the face of almost complete technical ignorance. Its greatest defect in their eyes was enough to spoil its every deatil, and that defect was primarily due to the fact that the war ended too soon! Yet they are as unable to recommend a constructive future policy as they are of finding good in whole-hearted effort. Granted that we had no commercial plants for the production of synthetic nitrates before the war, and that that lack then cost time and money, by all means let us now throw away the chances we have of systematically acquiring this knowledge.

Divergent Recommendations of the Committee

Majority Recommendations

1. The committee recommends that no further sums of money be paid the Air Nitrates Corporation or its subcontractors on account of its various contracts for the building of Nitrate Plants Nos. 2, 3, and 4 at this time, but that all sums claimed to be due and owing by the Government be retained; that civil suits be instituted against the Air Nitrates Corporation by the United States to recover such sums as shall reasonably compensate the United States for the failure of the Air Nitrates Corporation to perform its said contracts, or that the said Air Nitrates Corporation be compelled to sue for recovery in the Court of Claims, or other proper forum, where the Government may, by set-off, counterclaim, or recoupment, litigate the matters herein mentioned, or that the United States pursue such remedies concurrently, as may be decided by the Attorney-General of the United States.

2. The committee recommends that the materials stored by the Government in Nitrate Plants Nos. 3 and 4 be at once removed to other storehouses of the Government, that said plants be, as soon as possible, salvaged and sold to the best advantage, and that all landowners who have not been paid for lands purchased, taken, or damaged for said plants be compensated for the same.

3. That Nitrate Plant No. 1 be kept in a standby condition for the present with a sufficient force to guard and maintain the same, subject to such experimental use thereof, from time to time, as is necessary in developing nitrate processes or perfecting the said plant. That 1,200 acres of land not now used in said plant be sold at its fair market price; that the houses built in connection with said plant, where the same are not used to house officials or employees of the United States, be leased at fair rentals, notwithstanding the opposition of the Sheffield Chamber of Commerce or any other body.

4. Your committee recommends that Nitrate Plant No. 2 be leased by the War Department on such terms as will secure its continuance as a plant capable of producing fixed atmospheric nitrogen, and with reservations permitting the use of the same by the Government in time of war or threatened war, reserving to the Government a reasonable regulation of prices, and providing for the sale of the product on the general market direct to the consumer, including farmers in the United States, and that if this cannot be done, that the plant be kept in a standby condition until Congress shall determine upon a policy as to the future of said plant.

5. That no further funds should be expended by the War Department on the Muscle Shoals plant, and no further appropriations for alterations, changes, or additions to said plant should be made by Congress for the use of the War Department or any agency of the Government acting under or through said War Department, until some policy as to the future of said plant shall be determined upon by Congress.

Minority Recommendations

1. Not having any exact knowledge from the testimony adduced of the status of the settlements or negotiations looking to a settlement of the contracts with the Air Nitrate Co., having no definite information of the claims and counterclaims of the parties thereto, we do not feel ourselves to be in any position to offer any intelligent advice as to their settlement or as to the procedure that should be followed by the War Department or the Department of Justice. We are content to leave this executive matter to the executive departments whose duty it is to attend thereto, and direct our attention to the performance of our own duties in the legislative branch. Should occasion arise for the exercise of the constitutional powers and duties of the legislative branch, we shall try to inform ourselves and aid in the way that may seem to us to be the proper exercise of those functions.

2. There is nothing in the record nor have we any information from any extraneous source, upon which we are able to predicate any advice as to the removal of the materials now in storage in the buildings at Plants 3 and 4. Whether the Government has other storage facilities that can be economically utilized, we have no idea, nor have we any information whatever as to the costs that would accrue for freight, handling and other necessary activities incident to removal. We see no necessity for any recommendation as to an action concerning the matter, particularly since we have no information of the various elements involved.

We have heretofore concurred in a measure with finding 38, touching the matter of salvage and sale of plants 3 and 4, and have stated our belief that any legal obligations of the Government relative to the lands and landed rights acquired by it, if any are still outstanding, should be liquidated and paid. We have no reason to assume that this will not be done or that any recommendation is necessary or within the duty of the legislative branch of the Government. Whatever of appropriation may be necessary for the discharge of the Government's obligations will, we assume, be properly brought before the House by the Appropriations Committee.

3. There is no objection upon our part to the opinion implied in recommendation No. 4 as to what should be done with Plant No. 1, nor with the lands and houses, so far as we are informed of the facts. The 1,200 acres of surplus land, much of which was secured in contemplation of the erection of a powder plant, appears to be fairly good land for farming purpose and, so far as we know, the Government has no present need for it. These lands were acquired at a very reasonable price, some of them being donated outright. What the market conditions are now we do not know. Good business judgment should be used in disposing of them, as it doubtless will be.

We see no very serious objection to the renting temporarily and until other disposition can be made of the houses built in connection with the plant not in use by officials and employees. Just how Uncle Sam may get along as a landlord we do not know, but he is a very versatile gentleman, capable of doing many things and doing them well.

We have no sympathy with the implied criticism of the Sheffield Chamber of Commerce for opposing this, if they do in fact oppose it, which we do not know as a fact, though we believe there was some intimation to that effect somewhere in the hearings or stated privately to the committee. Those at Sheffield who have properties for rent probably fear Government competition with non-taxable real estate upon which the people carry the insurance and are probably in the same mental attitude toward it as are the private producers, present and prospective, of fixed nitrogen toward the operation by the Government of Nitrate Plant No. 2, for the production of commercial fertilizer.

We see no occasion for any recommendation.

4 and 5. Recommendations 4 and 5 involve directly the legislative question discussed in the findings 28 to 37, inclusive, and 39, with regard to the future use of Nitrate Plant No. 2, and for the reasons there stated, the minority deem it improper to here discuss them.

Research Council, Chemical Division, Annual Meeting

The annual meeting of the Chemical Division of the National Research Council was held in Washington May 7 and 8. The first order of business was the election of officers and members for the ensuing term. The results of the elections were as follows: Chairman of the Division, F. G. Cottrell, of the Bureau of Mines; vice-chairman, Julius Stieglitz, of the University of Chicago; members of the executive committee, C. L. Alsberg, Bureau of Chemistry; A. B. Lamb, Harvard University; John Johnston, Yale University; W. D. Bancroft, Cornell University. The other members of the Division are: C. G. Derick, National Aniline & Chemical Co.; J. M. Francis, Parke, Davis & Co.; E. C. Franklin, Stanford University; Colin G. Fink, Chile Exploration Co.; A. V. Bleininger, Washington, D. C.; Charles H. Herty, New York; W. F. Hillebrand, Bureau of Standards; G. A. Hulett, Princeton University; Hugh K. Moore, Berlin, N. H.; Arthur A. Noyes, California Institute of Technology; Charles L. Parsons, Washington, D. C., and J. E. Teeple, New York.

Charles L. Parsons was appointed a delegate to represent the National Research Council at the meeting of the International Chemical Union to be held at Rome, Italy, in the last week of June.

Reports of Committees

A very comprehensive report on the activities of the committee on explosives was presented by Charles E. Munroe. Among the important problems investigated were: Corrosion of Rifle Bearings; Products of Combustion of TNT; Desensitizing of Explosives for Storage; Hexanitrodiphenylamine; Use of TNT in Blasting. Furthermore, considerable time has been spent on the index to the literature of explosives which will soon be completed.

The report of the committee on synthetic drugs was presented by Prof. Stieglitz. It was pointed out that a number of important synthetic drugs had been placed on the market during the course of the year. Dr. H. N. Holmes told of the activities of the committee on colloids. The outstanding feature in this report was the remarkably efficient method the committee resorted to in educating students and the public in general to the vast importance of colloid chemistry. Lectures, both scientific and popular, had been delivered in most of the large towns of the country before enthusiastic audiences. Nearly every chemical industry in the country is confronted with colloid problems, for example, the rubber industry, dyes and dyeing industries, ceramic, glass, oil, pharmaceutical products, yeasts, etc.

Progress in Various Fields

Dr. Bleininger reported upon the researches in ceramics. There are many basic problems still waiting for a satisfactory solution. For example, there is the problem of finding a suitable refractory for glass pots which will not be readily corroded by the molten glass. A fellowship was established recently at the University of Illinois; the research will be confined largely to the "Viscosity and Electrical Conductivities of Glasses."

Dr. Derick discussed the progress made in the methods of analytical organic chemistry. The importance of the introduction of physicochemical apparatus into organic laboratories was particularly emphasized. Dr. Bancroft reported upon the progress made on research in contact catalysis. Important investigations are being carried out at seven of our large university research laboratories. Hugh K. Moore submitted a detailed account on the activities of the committee on the international tables of constants. The revision of our patent laws was discussed by Messrs. Cottrell and Francis.

Problems Awaiting Solution

Dr. Bancroft, after summing up the work of the Division during the past year, presented to the members a most remarkable collection of problems of far-reaching importance that are patiently awaiting solution. To those who have had difficulties in finding suitable problems for research, it will be a startling revelation to look over the list prepared by Dr. Bancroft. There are significant lines of chemical research to be found in every industry and profession of the country. The most promising field of research appears to be the borderland. Let the chemist co-operate with the geologist in studying the origin and formation of petroleum, or why some clays are plastic and others are not. Let the chemist work hand in hand with the biologist in investigating nutrition problems. There are many vital problems of mutual interest to both physicist and chemist; there are others on the borderland of chemistry and medicine. "And why should the chemist develop the borderlands? It is because the chemist has had the best all-around training."

Public Utility Power Efficiency

The monthly reports of the U. S. Geological Survey show a very interesting relationship between the power production and the efficiency with which the fuels are used in the various public utility central stations throughout the country. The following tabulation shows the total power output and the efficiency expressed in kilowatts per ton of coal used, for each of the seven months for which reports have been made. Some of the variation is undoubtedly due to seasonal factors, but the principal factor is probably the greater percentage load factor during recent months as compared with the period about a year ago. These figures, of course, cannot be taken as absolute in their significance, but are a good indication of the general practice.

Month.	Millions of kw.-hr.	Efficiency. Kw.-hr. per ton of coal
February, 1919	1,834	586
March, 1919	1,842	580
April, 1919	1,718	594
July, 1919	1,929	636
October, 1919	2,240	645
January, 1920	2,575	643
February, 1920	2,327	632

Another interesting point shown by the figures is the relatively greater average efficiency of central stations in states where most of the power is generated at large plants. For example, in Pennsylvania, Illinois, Ohio and other states where large cities predominate, the efficiency is about 600 kw.-hr. per ton of coal or even higher, being nearly 800 in the case of New York and Michigan. On the other hand, in more sparsely settled states, such as North Dakota and Montana, the average is only 150 to 200 kw.-hr. per ton. This is a striking illustration of the large advantage which the proposed super-power plants, if installed, will have in substituting for existing central stations. When it is seen that the average for whole states is five times that for other states, one can readily believe that the estimated saving of 50 per cent of the coal now used in all central stations would be feasible if all were replaced by a super-power system.

Proposed Fertilizer Regulation

Gilbert N. Haugen of Iowa, chairman of the House of Representatives Committee on Agriculture, has proposed a bill entitled "United States fertilizer act" for fixing the standard, labeling, and marketing fertilizer.

In this act the term "fertilizer" is defined as "Any substance, including any combination or mixture, designed and fit for use in inducing increased crop yields when applied to the soil," but does not include animal manure in its natural or unmanipulated state.

In it the Secretary of Agriculture is empowered to establish standards for grades of fertilizers by which its quality and condition may be determined.

Invoices and container labels are to be marked with:

Name and address of manufacturer.
Net weight in pounds.
Per cent by weight of available N_2, P_2O_5 and K_2O.
Name of each ingredient carrying available N_2, P_2O_5 and K_2O, and the proportion of each such ingredient if more than one be included.
Percentage weight, and kind of each ingredient having fertilizer value other than ingredients containing available N_2, P_2O_5 and K_2O.
Grade of fertilizer compared to U. S. standard.
Other facts to prevent frauds.

After defining the matters of standards, labeling, information regarding bulk shipments, etc., the act proceeds to define the terms "misbranding," "adulteration," etc. Authority is given to the Department representatives to enter and inspect any factory or storehouse and to investigate any books or records of the fertilizer industry. The companies are also required to preserve full and accurate records and to answer any inquiry that duly accredited representatives of the Department may submit. It is also provided that the information secured through the operation of these inspectors, with the exception of "secret processes or formulas," shall be available for the use of either house of Congress at its request, and the Secretary of Agriculture is given authority to cause such information to be published from time to time.

Judging from the difficulty encountered by the Government in fixing standards on grain and enforcing other such laws, serious apprehension exists on the fixing of standards on fertilizer. Moreover, the multiplicity of different brands (208 being listed in a single state report, all having the composition of 10 per cent phosphoric acid, 2 per cent ammonia and 2 per cent potash) and the fact that they are taxable have led to a system of registration and inspection fees imposed on the industry by different states whereby the states derive a considerable revenue. In fact, many of the state colleges and agricultural schools which now are either entirely or partially supported from this income would be seriously crippled were this revenue cut off.

Uniformity of requirements and labeling would protect the consumer against fraud and assure him a product of known standard strength. It would also tend to decrease the needlessly large number of brands, in which there is not enough difference in composition to affect plant growth seriously. Manufacturers of fertilizers who now have difficulty in doing an interstate business, because of complexity of regulations, would also be enabled to carry on their trade with greater ease.

On the other hand, the passage of this bill would mean a heavy financial loss to those institutions which derive a considerable income from taxes on fertilizers as now sold, until many state laws could be properly amended.

National Fire Protection Association Meeting

At the twenty-fourth annual meeting of the National Fire Protection Association held in Chicago May 4 to 6, 1920, the committee on hazardous chemicals and explosives presented a report covering regulations for the storage, handling and use of pyroxylin plastics in factories making articles therefrom. The report covered these substances, whether used in the form of raw materials, stock in the process of manufacture, unfinished or finished products or scraps, and the use and storage of nitro-cellulose film.

The term pyroxylin plastics was held to mean and include any plastic substance, material or compound having soluble cotton or similar nitro-cellulose as a base, and thus includes celluloid, fiberloid, pyralin, viscoloid and similar products, whether in the form of blocks, slabs, sheets, tubes or fabricated shapes, as well as lacquers, enamels, paints, thinners, cement and dope. Copy of the full report can be secured from the secretary-treasurer, F. H. Wentworth, 87 Milk St., Boston, Mass. The committee on gases also presented a tentative report for the regulation of refrigerating machines and refrigerants, and tentative regulations for the installation and operation of acetylene compressive plants.

New Amendment to Dye Bill Would Provide an Automatic Tariff

Senator Moses has offered an amendment to the dye bill which eliminates the embargo system and provides for an automatic tariff which is to be the difference between the price of a foreign article and the price of a similar article made domestically plus 20 per cent. He cites examples as follows: If foreign dye cost $2 per lb. to import and the fair selling price of a similar dye made domestically is $4, the tariff would be $2 plus 20 per cent of the home market value, or 80c., bringing the price of the imported article up to $4.80. If the price of the imported article were 15c. per lb. and the price of the home article $4, the tariff would be $3.85 plus 20 per cent. Senator Moses says that his proposal "is automatic and elastic and adjusts itself to every price and at all times places the price of a foreign dye 20 per cent above the price of a similar domestic dye."

The bill also provides that no person can bring in more than enough dyes at one time to suffice him for the current year. It contains a provision for ascertaining prices within the United States, the same as prices now are ascertained in foreign countries. This, Senator Moses thinks, would give absolute protection to the dye industry without embarrassing the textile industries with licenses, permits and embargoes.

Chemists' Club Elects Officers

At the annual meeting of the Chemists' Club held May 5, the following officers were re-elected:

President, Ellwood Hendrick; vice-president, resident, William F. Hoffmann; vice-president, non-resident, V. G. Bloede; secretary, J. R. M. Klotz; treasurer, Henry M. Toch; F. J. Metzger and T. R. Duggan, trustees.

Edgar F. Smith of Philadelphia, William H. Nichols of New York, John Uri Lloyd of Cincinnati, Edward Weston of Newark, H. le Chatelier of France, Ernest Solvay of Belgium, Giacimo Cimician of Italy and T. E. Thorpe of England were elected honorary members.

Lignite Carbonization Research Plant

After some months of investigation and negotiation, the United States Bureau of Mines has completed arrangements for a co-operative plan to carbonize lignite and develop the necessary information that it is hoped will "make possible a favorable technical and business report which shall stimulate duplication of such plants throughout lignite areas."

To this end a co-operative agreement has been made between the Bureau of Mines and John B. Adams and Fred Bremier, under which an appropriation of $100,000 and an additional $200,000 which is to be furnished by these individuals will be used for the construction of the plant required, and as a working capital for its operation. The plant will be installed at New Salem, N. D., on the site owned by the Consolidated Lignite Collieries Co., a subsidiary of which is to be organized by the two men who are contracting with the Government.

The plant contemplated will consist of a battery of ovens of new form which have been designed by the engineers of the Bureau of Mines, under the direction of O. P. Hood, chief mechanical engineer. This battery will, it is estimated, coke at least 100 tons of raw lignite per day and provide for complete recovery of the liquid and gaseous byproducts as well as for the handling of the char, from which it is planned to produce briquets. The briquetting plant will also be of special design, and it is to be an integral part of the plant, so that the char will be handled direct from the battery to the briquetting machine hoppers.

The substance of the agreement under which this work will be done is as follows:

Substance of the Agreement

It is proposed that the Bureau of Mines plan, erect and operate for a period a plant to carbonize brown lignite, briquet the solid residue, utilize the gas, recover tar and oils, measure and investigate all quantities, report on the process, including costs, selling prices and profits.

The plant would require three types of equipment:

1. Standard parts such as rail connections, coal-handling machinery, bins, driers, screens, briquetting equipment, etc., all of which can be purchased on the market from more than one source.

2. Special equipment more or less new in principle and development, part of which has resulted from the work of S. M. Darling.

3. Measuring, sampling and testing devices not usually necessary in a standardized commercial undertaking, but necessary in directing a new process and investigating performance.

It is proposed that the Bureau supply complete plans for the plant, have oversight over the construction and operation, and furnish items classified under 2 and 3.

It is proposed that the co-operating company approve the plans of construction, furnish items under classification 1, furnish all lignite and other raw materials, supplies and operating labor, market all products and conduct the business, leaving the Bureau funds for general oversight, investigation, control of the technical processes and the preparation of a report.

When the investigation fund is exhausted and the fixed structures sold, the co-operative company shall bid an amount equal to the replacement value, less reasonable depreciation.

American Zinc Institute Meeting

The second annual meeting of the American Zinc Institute was held at the Congress Hotel, Chicago, May 10 and 11. A large percentage of the 200 members attended, the tri-state, or Joplin district, being particularly well represented.

During the technical sessions George C. Stone delivered a paper on the differences in European and American zinc smelting practices. He noted that the American industry consumes ore from its own mines, while 80 per cent of that smelted in Europe is imported from Australia and north Africa. It is shipped in cargo with wool at a price which in normal times compares with freight rates on ores in the United States.

This importation permits a wide variety of selection of ores and the producer therefore designs his smelting plant with a certain shaped retort, to work at certain temperatures, with a specific grade of ore in view, and then purchases the ore to fit the furnace. In the American practice one general type of furnace is employed and used for the refining of any type of ore. This does not make for such economies as are enjoyed by the European concerns.

In Europe the fuel economy is very high due to the use of regenerative furnaces of both the recuperative and reversing type. From eight-tenths to one ton of coal is consumed per ton of ore in the European furnaces, while in America, where very few regenerative furnaces are in operation, from two to four tons of fuel per ton of ore is consumed.

The European concerns also exercise more care in the manufacture of their refractory materials in the retort, this being a direct result of the higher development of the ceramic industry among metallurgical producers.

The finished products of the European furnaces analyze much more consistently in impurities than is the case in the irregular American practice. The overall recovery in Europe is 84 per cent of the zinc contained in the ore, while in the United States it averages below 81 per cent. Should American firms adopt European practice, about 20,000 tons of ore would be saved per annum and several hundred thousand tons of coal. On the other hand, the American companies have more mechanical labor-saving devices than are used in Europe.

The discussion on this paper brought out the fact that most zinc producers are not familiar with the practice of mixing ores to get the maximum recovery of metal and the minimum slagging of retorts. Albert M. Plumb urged the further study of American ore mixtures from the point of view of iron, lime and silica content as it affects retort consumption. There are few ores in the United States that are not basic, and the recovery may be increased by more careful regulation of furnace temperatures.

Annual Meeting of the Chicago Chemists' Club

The first annual meeting of the Chicago Chemists' Club was held May 7, and the following officers were elected: President, William Hoskins; first vice-president, F. N. DeBeers; second vice-president, W. Lee Lewis; secretary, Paul VanCleef; treasurer, C. C. Kawin; trustees to serve for three years, Herbert N. McCoy and W. R. Smith.

Reports showed that the club now has a membership of eighty-nine, three of whom are non-residents.

Stamford Chemical Society Meeting

The eighth monthly meeting of the Stamford Chemical Society was held on Monday evening, April 26, at the Stamford High School Building. The two points of interest at the meeting were the election of officers and the rendering of a paper on "Allotropism Among the Metals," by Dr. F. H. Getman, president of the society. The paper was based largely upon the author's research work.

Allotropism Among the Metals

The phenomenon of allotropism was defined by Dr. Getman as the existence of an element in several physical forms; the chemical properties remaining the same. This phenomenon was first forcibly brought to the attention of the scientific world when a large shipment of tin, which was stored for a considerable time in Russia, was found in the form of a gray powder. Fraud was at once suspected. Chemical analysis, however, proved the material to be a high grade of tin.

As a result of recent investigations it has been shown that cadmium, zinc, lead, copper, tin, bismuth, antimony and sodium are in reality metastable systems consisting of two or more allotropic forms. The apparent stability of these metals is to be ascribed to marked retardation accompanying the reversible change of the different allotropic modifications in the neighborhood of their transition points. It is possible to accelerate these reversible transitions and to determine with considerable accuracy the transition temperatures and thus ascertain the conditions of stability of the metals. Obviously the physical and mechanical constants which have hitherto been determined refer to more or less complicated metastable systems.

The members of the society were very much interested to learn that Dr. Cohen, of the University of Utrecht, Netherlands, and Dr. Getman were both working, at the same time, on the allotropic forms of cadmium and that they both arrived at identical generalizations, although they worked from entirely different angles. While Dr. Cohen determined the density and some of the other physical properties of the different allotropic forms of cadmium for comparison, Dr. Getman determined with great accuracy the electrical potential between the different allotropic forms under various conditions.

U.S.P. Revision Organized

Manufacturers of drugs, pharmaceuticals and other chemicals listed in the U. S. Pharmacopœia should get in touch with the Committee on Revision which has just been organized and authorized to proceed on the preparation of the tenth edition of this volume. The U. S. Pharmacopœial Convention was held in Washington on May 11 and 12 for a discussion of the principles to be followed in this revision. Rules were adopted with respect to the object and scope of the work, doses, nomenclature, synonyms, purity and strength of pharmacopœial articles, international standards, physical constants and other related subjects. Some of the points of interest to chemical manufacturers are included in the following provisions:

In the case of newly admitted articles, it is recommended that such titles be chosen as are in harmony with general usage and convenient for prescribing; for synthetic chemicals, with lengthy or unwieldy names, the Committee of Revision shall be empowered to coin short euphonious titles, contracted, if possible, from the true chemical names, but in the case of chemicals of a definite composition the scientific name shall be given, at least as a synonym.

It is recommended that the standard temperature of 25 deg. C. (77 deg. F.) be retained in the revision (except in the case of alcohol) and that an alcoholometric table be inserted in Part II giving the percentage of alcohol at different temperatures.

It is recommended that the Committee of Revision be instructed to revise carefully the limits of purity and strength of the Pharmacopœial chemicals and preparations, for which limiting tests are or may be given. While no concession should be made toward diminution of medicinal value, an allowance should be made for unavoidable, innocuous impurities or variations due to the particular source or mode of preparation, or to the keeping qualities of the several articles.

The "Purity Rubric," which limits the percentage of innocuous impurities, as introduced in the previous revision, should be continued, and tests and requirements should be appended to each article for which a "Purity Rubric" is given.

It is recommended that a range of the content of absolute alcohol, by volume, be stated in the Pharmacopœia, accompanying the text, for each preparation containing alcohol.

It is recommended that official methods for taking physical constants shall be stated in the Pharmacopœia, and these shall apply to all articles in which physical constants are officially used, unless otherwise specifically excepted.

The Committee of Revision will have as its chairman Fullerton E. Cook, and Charles H. LaWall as its secretary. Prof. LaWall's address is 39 South 10th St., Philadelphia, Pa.

It is expected that the Committee of Revision will make public, for comment and criticism, an abstract of new descriptions and standards, and all important changes in preparations and standards proposed, before final adoption.

Washington Chemical Society Meeting

Dr. A. M. Comey addressed the Chemical Society of Washington on the subject of high explosives on May 13. He discussed the development of these materials from straight dynamite through gelatine dynamites, Judson powders, ammonia dynamites, ammonia-gelatine dynamites, permissible explosives and low-freezing dynamites. Mercury fulminate and its principal substitute lead azide (PbN_6) were also described. Methods of testing for strength, speed of detonation and sensitiveness of these and the various military high explosives, of which TNT is the preferred form, were described in detail.

One of the most striking developments in high-explosive work pointed out by Dr. Comey was the partial elimination of nitroglycerine from dynamites; about 40 per cent was an average figure fifteen or twenty years ago, whereas 20 per cent represents present practice.

The next meeting of the society will be held at the Geophysical Laboratory on May 27, at which time Dr. Arthur L. Day will address the membership. Dr. Day has recently resumed his active direction of the work of this laboratory. The various laboratories of the institution will be open for inspection on the evening of the meeting.

First Step Toward Department of Public Works

Passage by the Senate of a bill providing for a joint Committee on Reorganization of the Government Departments and the probability that similar action will be taken promptly by the House is regarded as a long step forward in the campaign to secure a Department of Public Works and other changes in the organization of administrative agencies in Washington. The bill provides for a study of the situation by three members of the Senate and three members of the House. The final report of the committee must be submitted at the opening of Congress in December, 1922. After speeches in favor of the resolution had been made by Senator Smoot, in immediate charge of legislation for the majority, and Senator Underwood, the Democratic leader, the Senate passed the measure by acclamation.

Annual Alumni Banquet of the Chemical Society of Brooklyn Tech

The annual dinner of the Chemical Society of Brooklyn Tech was held at the Chamber of Commerce Club on Saturday evening, May 15. About one hundred students and alumni were present.

Dr. B. Palmer Caldwell was called upon as the most recent addition to the faculty and spoke of the great difference between teaching in the country and in this metropolitan center. He took occasion to show that Dr. Pritchard's criticism of the research work carried out in American colleges and universities was entirely unjustified and that it was vital that much more liberal appropriations be made for this important work. Dr. William H. Nichols later emphasized the same point and showed that much harm would result from the curtailment of university research work.

Dr. Nichols, who is chairman of the board of trustees of the Polytechnic Institute, told the young men present of the tremendous development which had taken place in the chemical industry since he studied chemistry at the Brooklyn Tech. He gave it as his opinion that the developments in the chemical field in the immediate future would far surpass the achievements of the past. He also related some personal incidents in connection with the development of the American dye industry, particularly in the manufacture of aniline oil before the war, which proved to be of the greatest importance when it became necessary to manufacture smokeless powder for which diphenylamine is so essential.

The last speaker of the evening was Dr. Charles H. Herty, who spoke of the failure of the War Department to recognize the value of chemists at the beginning of the late war. He stated that the lack of appreciation of the chemist by the public in general was due largely to the unwillingness of the chemists themselves to inform the newspaper reporters on chemical matters. In speaking of the dye industry, Dr. Herty said that while it was only a small industry in itself it influenced a great many larger industries such as the textile and leather industries. He believed that the dye industry must be protected against foreign competition and vigorously attacked Senator Thomas for opposing the bill in Congress for that purpose. In concluding, Dr. Herty said that the dye industry is not only the main reserve in chemical warfare, but that the health of the people of America depends upon it.

The dinner was a most enthusiastic and delightful occasion. College songs and cheers added pep to the affair.

Book Reviews

CAST IRON IN THE LIGHT OF RECENT RESEARCH. By *William Herbert Hatfield, D.Met.* (Brown-Firth Research Laboratories, Sheffield). London: Charles Griffin & Co., Ltd., 1918. Second edition.

The first edition of this work, which appeared in 1912, attracted the attention in this country of metallurgists and others, not only on account of the original matter of interest and importance contained therein but also from the fact that it was, perhaps, the first fairly complete compilation in one volume of numerous researches and discoveries of very many workers during the last half century. Beginning practically with the classic writings of Prof. Thomas Turner on the influence of silicon in cast iron, published in 1885—an investigation which has had a profound effect upon modern methods in foundry practice and also even in the making of pig iron for foundry use—down to 1912, this book was a compendium of nearly all the important papers that were scattered throughout the journals of technical societies and periodicals up to that year.

The second edition has wisely adhered closely to the original scheme and has added four new chapters, increasing the number of pages from 244 to 286, not counting the indexes. Some idea of the thoroughness of this compendium may be gained from the fact that the index of names in the new edition contains no less than 140 names, from which, by the way, the author has modestly omitted his own name, though the book contains some of his original investigations, such as on page 89, *et seq.*, on the "Influence of Vanadium in Cast Iron."

The reviewer must remember that the work should be judged from the standpoint of metallurgical practices in Great Britain, which differ in some respects from our American practice. *E.g.*, the chilled cast-iron car wheel is peculiarly an American industry of vast proportions; there are probably today over 20,000,000 chilled cast-iron car wheels running on American railroads in freight service under cars with capacity up to 100,000 lb. and over, and the end is not yet reached!

Chapter V, on "The Influence of Manganese," shows its well-known action in neutralizing sulphur; its effect on the iron-carbon system; its influence on white cast iron and on gray cast iron; but no mention is made of the truly remarkable effect of adding a minute quantity of powdered 80 per cent ferromanganese in a ladle of molten high chilling car-wheel iron, increasing the strength over 30 per cent and decreasing the shrinkage in like proportion. It acts here as a desulphurizing and de-oxidizing flux. Since this process was published in 1888 (see *Journal of the Franklin Institute* for March, 1888), the method has been generally used with very great benefit in the manufacture of chilled cast-iron car wheels and other chilled castings. Chapter II devotes twenty pages to "The Influence of Silicon," and an elaborate discussion of the manner in which this element operates on cast iron, but no mention is made of the use of permanent iron molds in making machinable castings of exceedingly fine grain, free from blow holes, graphite and sand pits, etc. Since 1888 one foundry in Philadelphia has made an enormous number of machinable gray-iron castings in permanent iron molds, some of the original molds being still in use; this foundry has more than one hundred permanent iron molds. When it is realized that surface "chill" on a casting made in an iron mold (which may be not thicker than a sheet of tissue paper) will make the casting too hard to be readily machined, the fact that suitable treatment of the metal with silicon has made machinable castings in iron molds a *fait accompli* for thirty years, the value of that element may be more fully appreciated.

In conclusion, the reviewer would say that this book is one of great value to the metallurgist, the engineer and the educated foundryman.

ALEXANDER E. OUTERBRIDGE, JR.

Personal

CARL G. BARTH, a pioneer in the machinery-building industry, has been elected an honorary member of the Taylor Society. Only two other men have been thus honored by the Society, which is the national organization for the promotion of science in management, these being Frederick W. Taylor and Henri Le Chatelier, the engineer who developed scientific management in France.

J. E. BARTLETT has been elected president and general manager of Parke, Davis & Co., Detroit, Mich., succeeding the late Frank G. Ryan.

H. C. BELLINDER, general manager of the Chile Copper Co., arrived in New York from Chile on May 7.

Dr. WILLIAM BLUM, chemist in the National Bureau of Standards, spoke before the electroplaters of Providence, R. I., on May 11, describing the work which the Bureau is doing in this field, particularly the opportunities for research as a means for improving commercial electroplating practice.

Colonel MARSTON TAYLOR BOGERT, of the Department of Chemistry, Columbia University, has been elected president of the American Section of the Société de Chimie Industrielle of France. Prof. Bogert was president of the Society of Chemical Industry of England in 1913, and has been twice president of the American Chemical Society.

J. A. BRETZ has resigned as chief chemist and metallurgist of the Bettendorf Co. to take charge of the laboratory of the Southern Manganese Corp., Anniston, Ala.

C. E. BRODERS has resigned from the staff of the C. F. Burgess Labs. to take a position with the U. S. Auto Gear Shift Co., Eau Claire, Wis.

DONALD G. CLARK, district manager of the Firth Sterling Steel Co., spoke before the American Steel Treaters Society, May 19, on "The Heat Treatment of Stainless Steel."

Dr. COLIN G. FINK of New York lectured to the graduate students of Yale University on "The Organic Chemistry of Metal Carbides" and "Contact Catalysis."

L. W. JONES, dean of the college of engineering and architecture and dean of the school of chemistry, University of Minnesota, has resigned to become professor of organic chemistry, Princeton University, Princeton, N. J.

ROBERT M. KEENEY, electrometallurgist, Denver, Col., attended the convention of the National Electric Light Association at Pasadena, Cal., and read a paper on electric furnace practice.

C. H. KIDWELL, of the staff of the United States Geological Survey, has resigned to join the chemical staff of the Solvay Co., at Syracuse, N. Y.

DORSEY A. LYON is making a tour of the Western stations of the Bureau of Mines.

C. H. WOLFF was elected president of the American Zinc Institute at the annual meeting recently held in Chicago.

CLARENCE A. WRIGHT, hydrometallurgist for the Bureau of Mines at the Salt Lake station, has resigned, the resignation to take effect June 1. He expects to sail for Italy the latter part of June to engage in metallurgical work.

Obituary

HARLEY T. PROCTER, who for many years carried on the business of Procter & Gamble, manufacturer of Ivory Soap, died recently of diabetes at his home in New York City, in his seventy-third year. He had retired twenty-five years ago from active connection with the affairs of the company, which was founded by his father, William Procter. Mr. Procter was a member of the Metropolitan and Manhattan clubs.

Current Market Reports

The Non-Ferrous Metal Market

New York, May 24, 1920.—Price for copper is unchanged at 19¼c., which is regarded as being a rock-bottom quotation. Tin continued to decline, 52¼c. being the present figure. Other markets are steady.

	Cents per Lb.
Copper, electrolytic	19.25
Aluminum, 98 to 99 per cent	32@33
Antimony, wholesale lots	9.25
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	52.25
Lead, New York, spot	8.80
Lead, E. St. Louis, spot	8.50
Zinc, spot, New York	8.55
Zinc, spot, E. St. Louis	7.60

Zinc, scrap	4.25@ 4.50

The Iron and Steel Market

Pittsburgh, Pa., May 21, 1920.

While the number of rail strikers may have decreased somewhat in the past week or two, the traffic situation is distinctly worse, on account of congestion, and production of pig iron and steel has decreased rather than increased, being now hardly greater than it was when the strike effect was felt most seriously, toward the latter part of April.

The curtailment in operation is progressive, from the blast furnace through to the finishing departments. There is slightly less coke than there was a fortnight ago, due to increased car shortage at beehive coke ovens and at coal mines supplying byproduct ovens, hence there is less pig iron being produced. There is still less production of steel, with accumulation of pig iron at some works, either through stocks of steel having become uncomfortable or through there being a shortage of gas coal for open-hearth furnaces. Of the steel produced not all is going through the blooming mill, there being accumulation of ingots at some plants, while as to finishing departments some of the steel is being put into billets and sheet bars, as materials that can be most easily stocked. Finally, of the finished steel that is made a considerable percentage is not shipped, as the car supply is insufficient even for the reduced production.

The car supply is so poor now that there is no longer much question, from the steel mill viewpoint, of lines of communication being open to customers.

A rough guess as to the amount of steel now accumulated may be of interest. Only a guess can be made, but even that is suggestive. One starts with the ingot production

in March, when the rate was the heaviest since October, 1918. The American Iron and Steel Institute report, covering the output in that month of thirty companies which, in 1918, made 84.03 per cent of the country's total, indicated a rate in March of about 45,200,000 gross tons per annum. The normal ratio is 76 per cent for finished rolled steel, as reported in the statistics, to ingots. Applying 76 per cent, dividing by 52 and passing from the gross to the net ton, one finds a weekly rate of finished rolled steel production of 750,000 net tons, or 125,000 tons per working day. Thus far the computation is reasonably exact and accurate. Another fairly well-known fact is that the rail strike has an average life of about seven weeks to date, having begun in the Chicago district April 1, reaching the valleys and Pittsburgh about Monday, April 12. Assuming production to have averaged 80 per cent of the March rate and shipments 65 per cent of the production, the shipments were 52 per cent of the March rate, leaving 28 per cent at the mills, 28 per cent of 750,000 tons a week for seven weeks being 1,470,000 net tons. There was an accumulation of steel at mills on April 1, apparently large at the time, due to the car shortage earlier in the year, so that a fair guess would be more than 1,500,000 net tons of steel now at mills in equivalent of finished steel, but a part of it really in ingot, billet and sheet bar form awaiting finishing at a more convenient time when fuel is less scarce. On account of mill limitations that part of the stock will be some time getting worked off, while the finished product will also move slowly, at best, for the ending of the rail strike itself, whenever that occurs, will be followed by car shortage and only gradual relief from present congestion.

Markets Apathetic

Buyers of pig-iron and steel products are showing no interest whatever. They could, perhaps, be taking their cue from the stocks of material that have been accumulating, but undoubtedly they are greatly influenced by the very apparent unsettlement of business and financial conditions generally. Buyers of steel always keep an eye on the stock market and there has never been a free movement in steel buying when Wall Street was showing serious declines.

For several weeks the important but unanswered question has been how the consumption of steel was comparing with the production. There are cases of factories closing from lack of steel and other cases of factories running very well, and no comprehensive survey has been made. As noted in this report a week ago, if consumers have been maintaining operations to any extent by drawing upon stocks, and thus consuming more steel than is received, the stocks must have been accumulated at some time, and the only time was last February and March. However, one day last week, when the rail strike was about six weeks old, Ford made a new record for a day's output with 4,600 cars.

Prices

There is no declining tendency apparent in prices, except in prices for prompt steel, and that might be due to there being less bidding because prompt shipment might not mean anything like prompt delivery. In a quiet market, of course, the mills having the least business on books and therefore having the highest prices would naturally approach the end of their orders sooner than others, and would thus be moved to reduce prices. Mills that are booked for a few months have no incentive to reduce prices, it being axiomatic in the steel trade that, generally speaking, reducing prices does not stimulate buying. The exception is when buyers and sellers have played the "waiting game" for a long time. There are now predictions in some quarters that there will be no very active market in steel generally until prices have all declined to the Steel Corporation or Industrial Board level. No one predicts that that schedule of prices is in danger.

Pig-iron transactions are confined to small lots for early shipment, such business making the only market quotable, and thus the market is unchanged, though forward deliveries are not tested. Quotations are: Bessemer, $42.50; basic, $43; foundry, $44@$45, f.o.b. valley furnaces, freight to Pittsburgh being $1.40.

Ferro-Alloys

A few consumers of ferromanganese have run decidedly short, due in part to delay in receipt of ferromanganese purchased long ago in England, and the prompt market is still, with $250, delivered, readily obtainable, and perhaps up to $260, but the shipment must really be prompt, as the middle of the year is only six weeks distant and second half deliveries are merely firm at $200, delivered. Spiegeleisen is $72.50@$75, furnace, for spot, being both firm and quiet at that level. Electrolytic ferrosilicon is quiet at $78@$80, delivered, with 75 per cent not tested, but probably about $155. Bessemer ferrosilicon remains at $62.50 for 10 per cent, $65.80 for 11 per cent and $69.10 for 12 per cent, f.o.b. furnaces at Jackson and New Straitsville, Ohio.

The Chemical and Allied Industrial Markets

New York, May 21, 1920.

There has been little if any activity in the local market since the last report. While producers, in most instances, report a satisfactory supply of crude material, they are met with the difficult task of finding means to transport it from the sources or from intermediate points of shipment.

With plenty of alcohol at the distilleries, the obstacles confronting the shipper have brought a rise in the denatured product slightly above the dollar mark per gallon in less than carload lots, f.o.b. New York, and there are prospects of a further increase. Importation of *barium chloride*, in limited quantities, had been able to ease the demand, but frequent withdrawals by the German Government of permission to export have produced a growing scarcity. Current quotations in less than carload lots range from $175 to $200 per ton. *Glycerine*, with a steady demand, has shown an increase from the previous quotation of 24½@28½c. per lb. to 26½@28½c., and unless new sources and lower prices of crude oil are obtained there is little likelihood now of a return to the old prices. The same conditions affect *paraffine waxes*, where an increase in price has been the result. One of the leading manufacturers quotes crude match wax (white), 105-110 m.p., at 10c. per lb., a movement from 9½c., with like increases in other grades. *Zinc chloride*, *granular*, ranges up from 13½c. per lb. in less than carlots, one dealer securing spot goods at 15c. per lb. notwithstanding the scarcity of the product. There appears to be a sufficient supply of *sodium carbonate* in the vicinity, but conditions are such as practically to isolate it. *Sodium cyanide*, 96-98 per cent, continues to be quoted at 24@25c. per lb. despite a temporary shortage due to the accidental loss of one large shipment. Continued lack of raw material has caused a rise in price of *acetic acid*, 56 per cent, to $7.50@$8 per cwt. in carlots. There has been little movement in this or other acids, and with the exception of acetic, no revision of quotations.

Vegetable Oils

A marked decrease in the prices of domestic *linseed oil* has followed the lower quotations of the English product. Raw material in carlots is quoted today at $1.65 per gal. while the raw imported from England ranges in price from $1.45 to $1.50 in barrels. Domestic linseed oil, raw, in tank cars, shows a drop to $1.60 and a similar reduction is noted in carlot quotations of the boiled material. Higher cost of manufacture here will probably prevent the equalization of domestic and imported oils. At the same time, importation in quantities will continue so long as it aids substantially, as it has been doing, in restoring the English sovereign to its pre-war value. *Olive oil*, commercial, is now quoted at $3.10@$3.25, a sudden increase and due solely to the embargo placed by Spain.

Naval Stores

In anticipation of the arrival of the new product, prices of *rosin* have declined, but thus far it has been an almost impossible matter to secure shipments from the South. The B-D type in barrels of 280 lb. is quoted at $16.50@$18.75, *rosin oil* of the first run declining to 95c. per gal., second run, 88c., third run and fourth run, $1.00. *Turpentine* remains firm with little movement by shippers.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots

Arsenic, sulphide, powdered (red arsenic)	lb.	.23 – .24	—
Barium chloride	ton	150.00–160.00	1.75 – 2.00
Barium dioxide (peroxide)	lb.	.21 – .23	.24 – .25
Barium nitrate	lb.	.10 – .11	.11 – .12
Barium sulphate (precip.) (blanc fixe)	lb.	.04½ – .05	.05½ – .06
Bleaching powder (see calcium hypochlorite)		—	—
Blue vitriol (see copper sulphate)		—	—
Borax (see sodium borate)		—	—
Brimstone (see sulphur, roll)		—	—
Bromine	lb.	.85 – .90	1.00 – 1.05
Calcium acetate	cwt.	3.50 – 3.55	—
Calcium carbide	lb.	.04½ – .04½	.04¾ – .05½
Calcium chloride, fused, lump	ton	23.00 –25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02¼
Calcium hypochlorite(bleaching powder)	cwt.	4.00 – 4.25	4.50 – 5.00
Calcium peroxide	lb.	—	1.50 – 1.70
Calcium phosphate, monobasic	lb.	—	.75 – .80
Calcium sulphate, pure	lb.	—	.25 – .30
Carbon bisulphide	lb.	.08 – .09	.10 – .11
Carbon tetrachloride, drums	lb.	.11 – .11½	.12 – .15½
Carbonyl chloride (phosgene)	lb.	—	.80 – 1.05
Caustic potash (see potassium hydroxide)		—	—
Caustic soda (see sodium hydroxide)		—	—
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.09 – .09½	.10 – .10½
Chloroform	lb.	.30 – .35	.36 – .38
Cobalt oxide	lb.	—	2.00 – 2.05
Copperas (see iron sulphate)		—	—
Copper carbonate, green precipitate	lb.	.27 – .28	.29 – .31
Copper cyanide	lb.	—	.65 – .70
Copper sulphate, crystals	lb.	.08¼ – .09	.09 – .09¼
Cream of tartar (see potassium bitartrate)		—	—
Epsom salt (see magnesium sulphate)		—	—
Ethyl Acetate Com. 85%	gal.	1.35 –	1.40 –
Ethyl Acetate pure (acetate ether 98% to 100%		—	1.75 –
Formaldehyde, 40 per cent (nominal)	lb	38 – 40	57 – .65
Fusel oil, ref	gal.	—	5.25 – 6.00
Fusel oil, crude (nominal)	gal.	—	—
Glauber's salt (see sodium sulphate)		—	—
Glycerine	lb.	—	.26½ – .28½
Iodine, resublimed	lb.	4.30 – 4.35	4.40 – 4.45
Iron oxide, red	lb.	—	.03 – .20
Iron sulphate (copperas)	cwt.	1.50 – 1.75	1.80 – 2.00
Lead acetate, normal	lb.	—	.13⅝ – .15¾
Lead arsenate (paste)	lb.	.11 – .12	.13 – .17
Lead nitrate, crystals	lb.	—	.90 – 1.00
Litharge	lb.	.14 – .15	.15½ – .16
Lithium carbonate	lb.	—	1.50 –
Magnesium carbonate, technical	lb.	.12 – .14	.15 – .16
Magnesium sulphate, U. S. P	100 lb.	3.50 – 3.55	4.00 – 4.50
Magnesium sulphate, commercial	100 lb.	—	3.25 – 3.60
Nickel salt, double	lb.	—	.14 – .16
Nickel salt, single	lb.	—	.16 – .18
Phosgene (see carbonyl chloride)		—	—
Phosphorus, red	lb.	.50 – .55	.60 – .65
Phosphorus, yellow	lb.	—	.35 – .37
Potassium bichromate	lb.	.36 – .37	.45 – .46
Potassium bitartrate (cream of Tartar)	lb.	.53 – .56	.57 – .58
Potassium bromide, granular	lb.	.80 – .85	.90 – .95
Potassium carbonate, U. S. P	lb.	—	.85 – .88
Potassium carbonate, crude	lb.	.21 – .25	.26 – .28
Potassium chlorate, crystals	lb.	.14 – .16	.21 –
Potassium hydroxide (caustic potash)	lb.	.28 – .29	.31 – $ .32
Potassium iodide	lb.	—	3.35 – 3.60
Potassium nitrate	lb.	.15 – .17	.19 – .21
Potassium permanganate	lb.	—	.85 – .95
Potassium prussiate, red	lb.	$0.90 – $1.00	$1.05 –
Potassium prussiate, yellow	lb.	.32 – .36	.36½ – 0.37½
Potassium sulphate (powdered)	ton	$225.00 –240.00	—
Rochelle salts (see sodium potas. tartrate)		—	—
Salammoniac (see ammonium chloride)		—	—
Sal soda (see sodium carbonate)		—	—
Salt cake	ton	28.00 –32.00	—
Silver cyanide (nominal)	oz.	—	1.25 –
Silver nitrate (nominal)	oz.	—	.74 – .76
Soda ash, light	100 lb.	—	3.50 – 3.60
Soda ash, dense	100 lb.	—	3.55 – 3.65
Sodium acetate	lb.	.08½ – .09	.09½ – .12
Sodium bicarbonate	100 lb.	2.25 – 2.60	2.75 – 3.50
Sodium bichromate	lb.	.33 – .35	.36 – .37
Sodium bisulphite (nitre cake)	ton	7.00 – 7.50	8.00 – 10.00
Sodium bisulphite Powered	lb.	.06 – .06½	.07 – .10½
Sodium borate (borax)	lb.	.09 – .10	.11 – .12
Sodium carbonate (sal soda)	100 lb.	1.60 – 1.80	1.80 – 2.00
Sodium chlorate	lb.	—	.10 – .11
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.18 –	.19 – .20
Sodium hydroxide (caustic soda)	100 lb.	5.00 – 6.00	6.25 – 6.50
Sodium hyposulphite	lb.	—	.03 – .04
Sodium molybdate	lb.	2.50 –	3.25¾ –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.20 – .21	.24 – .25
Sodium peroxide, powdered	lb.	.32 – .35	.35 – .40
Sodium phosphate, dibasic	lb.	.03¾ – .04½	.04½ – .05
Sodium potassium tartrate (Rochelle salts)	lb.	—	.39 – .40
Sodium prussiate, yellow	lb.	.23 – .02	.31 – .32
Sodium silicate, solution (40 deg.)	lb.	.01½ – .02	.02 – .02¼
Sodium silicate, solution (60 deg.)	lb.	.02¼ – .03	.04 – .05
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.60 – 1.70	1.75 – 2.25
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	.09 – .10	.10½ – .11
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.23 – .24	.25 – .26
Sulphur chloride	lb.	.05¾ –	.06 –
Sulphur, crude	ton	22.00 –	—
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –	.46 – .50
Tin oxide	lb.	.60 – .63	.65 –
Zinc carbonate, precipitate	lb.	.16 – .18	.19 – .20
Zinc chloride, gran	lb.	.13 –	.13½ – .17
Zinc cyanide	lb.	.49 –	.50 – .60
Zinc dust	lb.	.12½ –	.13 – .15
Zinc oxide, U. S. P	lb.	.18 – .19	.20 – .21
Zinc sulphate	lb.	.03½ – .03¾	.04 – .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	—	$1.25
Alpha naphthol, refined	lb.	—	1.45
Alpha naphthylamine	lb.	.65 —	.70
Aniline oil, drums extra	lb.	.35 —	.40
Aniline salts	lb.	.45 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.90 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.35 —	1.40
Benzidine, sulphate	lb.	1.20 —	1.25
Benzoic acid, U.S.P	lb.	.90 —	1.10
Benzoate of soda, U.S.P	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.31
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate (nominal)	lb.	.50 —	.65
Beta naphthol, sublimed (nominal)	lb.	—	1.00
Beta naphthol, tech (nominal)	lb.	.75 —	.85
Beta naphthylamine, sublimed	lb.	2.25 —	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 —	.19
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.10 —	1.20
Cresylic acid, 95-97%, dark, in drums	gal.	1.00 —	1.05
Cresylic acid, 50%, first quality, drums	gal.	.65 —	.75
Dichlorbenzol	lb.	.08 —	.10
Diethylaniline	lb.	—	1.80
Dimethylaniline (nominal)	lb.	1.50 —	1.55
Dinitrobenzol	lb.	.30 —	.37
Dinitroclorbenzol	lb.	.30 —	.35
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.40 —	.45
Dinitrotoluol	lb.	.40 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine (nominal)	lb.	—	.85
H-acid (nominal)	lb.	2.25 —	2.50
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.70 —	1.85
Naphthaline crushed, in bbls. (250 lb.)	lb.	.15 —	—
Naphthaline, flake	lb.	.15 —	.17
Naphthaline, balls	lb.	.16 —	.18
Naphthionic acid, crude	lb.	.75 —	.85
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.40 —	.50
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.25 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.35 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.08 —	.12
Paranitraniline	lb.	—	1.65
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.60 —	3.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.65 —	.75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	4.25 —	4.50
Resorcin, pure	lb.	6.25 —	6.75

Salicylic acid, tech., in bbls. (110 lb.)	lb.	$0 50	—	$0 52
Salicylic acid, U. S. P.	lb.	55	—	60
Salol	lb.	.90	—	1 00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25	—	.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.23
Sulphanilic acid, crude	lb.	.28	—	.32
Toluidine	lb.	1 70	—	2 00
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.32
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	....
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0 36	—	$0 39
Beeswax, refined, light	lb.	39	—	.40
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1, (nominal)	lb.	.93	—	.95
Carnauba, No. 2, regular (nominal)	lb.	.85	—	.88
Carnauba, No. 3, North Country (nominal)	lb.	.44	—	.45
Japan	lb.	.21	—	.22
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09½	—	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	....	—	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	11½	—	12
Paraffine waxes, refined, 128-130 m.p.	lb.	.13	—	.14
Paraffine waxes, refined, 133-135 m.p.	lb.	.15½	—	.16½
Paraffine waxes, refined, 135-137 m.p.	lb.	.17½	—	.18½
Stearic acid, single pressed	lb.	.25	—	.26
Stearic acid, double pressed	lb.	.26	—	.27
Stearic acid, triple pressed	lb.	.28	—	.29

NOTE—Quotations on paraffine waxes are nominal

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.75
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.38
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots

Rosin B-D, bbl.	280 lb.	115 95	—	$18 75
Rosin E-I	280 lb.	18 75	—	19 00
Rosin K-N	280 lb.	19 00	—	21 00
Rosin W. G.-W. W.	280 lb.	20 50	—	21 50
Wood rosin, bbl.	280 lb.	17 50	—	18 50
Spirits of turpentine	gal.	....	—	2 45
Wood turpentine, steam dist.	gal.	2 35	—	2 40
Wood turpentine, dest. dist.	gal.	....	—	2 00
Pine tar pitch, bbl.	200 lb.	8 40	—	8 50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14 50	—	15 00
Retort tar, bbl.	500 lb.	15 00	—	15 50
Rosin oil, first run	gal.	.85	—	.95
Rosin oil, second run	gal.	.88	—	.97
Rosin oil, third run	gal.	1 00	—	1.05
Rosin oil, fourth run	gal.	1 05	—	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal	$0 40
70-72 deg., steel bbls. (85 lb.)	gal	38
68-70 deg., steel bbls. (85 lb.)	gal	37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal	29

Crude Rubber

Para—Upriver fine	lb.	$0 39½		$0 40
Upriver coarse	lb.	.29	—	29½
Upriver caucho ball	lb.	.30½	—	....
Plantation—First latex crepe	lb	....	—	38
Ribbed smoked sheets	lb.	.37½	—	.38
Brown crepe, thin, clean	lb.	....	—	35
Amber crepe No. 1	lb.	....	—	40

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb	$0.18½	—	$0.20
Castor oil, AA, in bbls.	lb	.20	—	.22
China wood oil, in bbls.	lb.	.22½	—	23½
Cocoanut oil, Ceylon grade, in bbls	lb.	.18½	—	.18¾
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.19½	—	.20½
Corn oil, crude, in bbls	lb.	.17¼	—	18
Cottonseed oil, crude (f.o.b. mill)	lb	15½	—	16
Cottonseed oil, summer yellow	lb.	.19	—	19
Cottonseed oil, winter yellow	lb.	.21	—	.22
Linseed oil, raw, car lots (domestic)	gal	1 65	—	....
Linseed oil, raw, tank cars (domestic)	gal.	1 60	—	....
Linseed oil, boiled, car lots (domestic	gal.	1.67	—	....
Olive oil, commercial	gal.	3 10	—	3 25
Palm, Lagos	lb.	13½	—	14
Palm, bright red	lb.	.13	—	13½
Palm, Niger	lb.	.12	—	13
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.16½	—	17½
Peanut oil, refined, in bbls	lb.	.22	—	24
Rapeseed oil, refined in bbls	gal	1 70	—	1 72
Rapeseed oil, blown, in bbls	gal.	1 80	—	1 82
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.17	—	18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.13	—	13½

FISH

Winter pressed Menhaden	gal.	$1 17	—	$1 18
Yellow bleached Menhaden	gal.	1 20	—	1.22
White bleached Menhaden	gal.	1 23	—	1 24
Blown Menhaden	gal.	1.30	—	1.32

Miscellaneous Materials

All f. o. b. New York Unless otherwise stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	$20 00	—	$22 00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	12 00	—	15 00
Barytes, crude, 88% (@ 24% ba., Kings Creek	net ton	8 00	—	10 00
Blanc fixe, dry	lb.	3½	—	4
Blanc fixe, pulp	ton	60 00	—	80 00
Casein	lb.	15	—	18
Chalk, English, extra light	lb.	05	—	07
Chalk, English, light	lb.	04½	—	06
Chalk, English, dense	lb.	04	—	05
China clay (Kaolin) crude, f.o.b. Plen, Va	net ton	8 00	—	12 00
China clay (Kaolin), imported, lump	ton	25 00	—	35 00
China clay (Kaolin), imported, powdered	ton	50 00	—	60 00
Feldspar (nominal) f.o.b. N. Y. State	ton	15 50	—	18 00
Feldspar, crude, f.o.b. Maryland and North Carolina, points	net ton	7 50	—	8 00
Feldspar, ground, f.o.b. Baltimore	net ton	18 00	—	25 00
Fire clay, f.o.b. Baltimore	net ton	5 00	—	7 00
Fuller's earth, domestic, powdered	ton	25 00	—	30 00
Fuller's earth, imported, powdered	ton	35 00	—	40 00
Graphite (dust polish grade 30%) Ashland, Ala	lb.		—	0 01
Graphite (dust facing grade 50%) Ashland, Ala	lb.		—	0 01½
Graphite, crucible, 85% carbon Ashland, Ala	lb.		—	07
Graphite, crucible, 90% carbon Ashland, Ala	lb.		—	08½
Pumice stone, imported	lb.	03	—	06
Pumice stone, domestic	lb.	02½	—	....
Quartz (acid tower) fist to head, f.o.b. Baltimore	net ton		—	10 00
Quartz (acid tower) 1½ to 2 in., f.o.b. Baltimore	net ton		—	14 00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton		—	17 00
Shellac, orange, fine nominal	lb	1 50	—	....
Shellac, orange, superfine	lb	1 60	—	1 65
Shellac, A. C. garnet	lb	1 30	—	1 35
Soapstone	ton	15 00	—	25 00
Talc, domestic	ton	20 00	—	60 00
Talc, imported	ton	60 00	—	70 00

Refractories

Following prices are f.o.b. Works:

Chrome brick	net ton	$75-80 at Chester, Penn
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn
Magnesite, dead burned	net ton	50-55 at Chester, Penn
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f. o. b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200 00	—	$250 00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20	—	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb	.21	—	.22
Ferro-manganese, 70-80% Mn.	gross ton	200 00	—	250 00
Spiegeleisen, 16-20% Mn	gross ton	73 00	—	75 00
Ferro-molybdenum, per lb. of Mo	lb.	2 25	—	2 75
Ferro-silicon, 50%	gross ton	80 00	—	90 00
Ferro-silicon, 75%	gross ton	175 00	—	200 00
Ferro-silicon, 10-15%	gross ton	60 00	—	65 00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	90	—	1 10
Ferro-uranium, 35-50% of U	lb.	7 00	—	....
Ferro-vanadium, 30-40% per lb. of contained V.	lb	6 50	—	7.75

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3, f.o.b. Atlantic seaboard	unit	$0 70	—	$0.85
Chrome ore, 48% and over †	unit	....	—	....
Coke, foundry, f.o.b. ovens	net ton	12 00	—	14 00

Mill, Pittsburgh

Beams and channels, 3 to 15 in.	100 lb.	$2 45	—	$4 00
Angles, 3 to 6 in., ¼-in. thick	100 lb.	2 45	—	4 00
Tees, 3 in. and larger	100 lb.	2 45	—	4 00
Plates	100 lb.	2 45	—	4 00
Rivets, structural, 5/8 in. and larger	100 lb.	4 50		
Rivets, cone head for boilers, ½ in. and larger	100 lb.	4 50		
Sheets, No. 28 black	100 lb.	4 45	—	5 50
Sheets, No. 10 base, galvanized	100 lb.	5 45	—	6 50
Sheets, No. 28 galvanized	100 lb.	5 10	—	5 50

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage. For galvanized corrugated sheets, add 110c. all gages.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

SAN DIEGO—The Citrus Soap Co., 9th and K. Sts., is building a 4-story, 200x300-ft. modern manufacturing plant at Union and Market Sts. Estimated cost, $200,000.

Illinois

ROCKFORD — The Emerson-Brantingham Co., South Independence Ave., plans to construct a 1-story, 80x200-ft. annealing plant, cost, $30,000 and a 1-story, 41x100-ft. core room, cost, $9,000.

Iowa

AMES—A. B. Maxwall, city clk., City Hall, will receive bids until June 7 for the construction of a sewage treatment plant consisting of a pumping plant, Imhoff tank, sludge bed, a 100x148-ft. trickling filter, etc. Noted March 10.

COIN—The School Bd. is having plans prepared for the construction of a 3-story, 65x120-ft. school building. A chemical laboratory will be installed in same. Estimated cost, $135,000. C. S. Buchtel, pres., W. Gordon, 319 Hubbell Bldg., Des Moines, archt.

GLIDDEN—The Bd. Educ. has awarded the contract for the construction of a 3-story, 90x162-ft. school building, to W. F. Kucharo & Co., 622 Hubbell Bldg., Des Moines. A chemical laboratory will be installed in same. Estimated cost, $170,654. Noted May 12.

WATERLOO—Deere & Co., 1325 Third Ave., Moline, Ill., has awarded the contract for the construction of a group of foundry buildings including a 120x200-ft. foundry addition, etc., to the Scales Constr. Co. Foundry equipment will be installed in same. Estimated cost, $400,000.

Maryland

LANSDOWNE—The Natl. Steel Rolling Co., 203 Keyser Bldg., Baltimore, will receive bids until June 10 for the construction of a 1-story, 70x140-ft. steel-rolling mill. The company is in the market for rolling mill machinery, etc. Estimated cost, $100,000.

Massachusetts

BROCKTON—The O. A. Miller Tree Co., c/o G. L. Falk, archt., 63 Main St., has awarded the contract for the construction of a 3-story, 55x160-ft. dry kiln plant on Cherry St., to the George Howard & Sons Co., 153 North Main St. Estimated cost, $50,000. Noted April 14.

FLORENCE—The International Silver Co., 48 State St., Meriden, Conn., plans to build a 1-story, 40x86-ft. forge shop. Estimated cost, $25,000.

WAKEFIELD—The Bd. Educ. will soon award the contract for the construction of a 3-story, 210x250-ft. high school on Main St. A chemical laboratory will be installed in same. Estimated cost, $450,000. F. I. Cooper Corp., 33 Cornhill St., Boston, archt.

WEST SPRINGFIELD (Springfield P. O.)—The New England Box Co., Greenfield, has awarded the contract for the construction of a 1-story manufacturing building on Cold Springs Ave., to the E. F. Carlson Co., 244 Main St., Springfield. Estimated cost, $150,000.

WORCESTER—The Rogers Drop Forging Co., Frank St., has awarded the contract for the construction of a forge plant including a 1-story, 60x85-ft. sand blasting building, 1-story, 120x150-ft. forge shop, etc., to the E. D. Ward Co., 82 Foster St. Estimated cost, $125,000.

Michigan

DETROIT—The Acme White Lead & Color Wks., 1768 St. Aubin St., is in the market for machinery including 300 mills to be used in the grinding of paint for the automobile industry.

DETROIT—The Detroit Graphite Co., 12th St., engaged Smith, Hinchman & Grylls, archts., 710 Washington Arcade Bldg., to prepare plans for the construction of a 2-story factory building for the manufacture of paint, on 12th St. Estimated cost, $50,000.

DETROIT—M. E. Wellhalm, 225 Northwestern Ave., is in the market for brick-making equipment for a modern sized outfit.

KALAMAZOO—The Sutherland Paper Co., Lincoln St., has awarded the contract for the construction of a 3-story, 96x375-ft. paper mill, to O. F. Miller.

MUSKEGON HEIGHTS (Muskegon P. O.)—The City Water Comn. engaged Hoad & Decker, engrs., Engineering Bldg., Ann Arbor, to prepare plans for the construction of a well and filtration galleries having a daily capacity of about 500,000 gal. Estimated cost, $50,000.

Minnesota

ELLSWORTH—The city rejected all bids for the construction of sanitary sewers, disposal works including a disposal tank, sludgebed, etc. Estimated cost, $40,000. Druar & Smith, Globe Bldg., St. Paul, engrs. Noted April 21.

Missouri

JEFFERSON CITY—The City Council will soon award the contract for the furnishing of labor and material including an Imhoff tank, etc., for the construction of 3,650 lineal ft. of sanitary sewers, etc.

New Jersey

HALEDON — The Mayor and the Borough Council will receive bids until June 7 for the construction of a reservoir, dam, filter house and clear water basins, etc.

NEWARK—The Bd. Educ., City Hall, will have plans prepared for the construction of a school building on Oliver St. A chemical laboratory will be installed in same. Estimated cost, $400,000. John H. and Wilson C. Ely, Firemans Trust Bldg., archts.

NEWARK—The Bd. Educ., City Hall, will receive bids until June 8 for the construction of a 3-story, 219x222-ft. school building on 1st and 2nd Aves. A chemical laboratory will be installed in same. Estimated cost, $1,125,000. John H. and Wilson C. Ely, Firemans Trust Bldg., archts.

New York

ALBANY—F. S. Greene, comn., and Irving A. Huie, secy., 55 Lancaster St., will receive bids until June 7 for the furnishing and delivering of lignin or sulphite liquor material for use by the State Highway Comn. in the maintenance and repair of improved highways.

BROOKLYN—J. E. Nitchie, archt., 63 Park Row, New York City, will soon award the contract for the construction of a 4-story, 50x100-ft. factory addition at 73 Otsego St., for the Keystone Varnish Co., 91 Otsego St. Estimated cost, $85,000. Noted April 14.

BROOKLYN—The Valentine Co., 346 Manhattan Ave., has awarded the contract for altering a steel factory for the manufacture of paints on Richardson, Bayard and Lorimer Sts., to Barney Ahlers, 110 West 40th St., New York City. Estimated cost, $50,000.

BUFFALO—The Kimberley Clark Paper Co., Pine St. and Packard Rd., Niagara Falls, has awarded the contract for the construction of a 2-story, 145x458-ft. factory building, to the Lackawanna Bridge Co., Bell and Abby Sts. Estimated cost, $700,000.

BUFFALO—The Natl. Carbon Co., College Ave., Niagara Falls, has awarded the contract for the construction of a 1-story, 25x300-ft. factory, to the John W. Cowper Co., Inc., Fidelity Bldg. Estimated cost, $100,000.

BUFFALO — The Paper Convertible Corp., Niagara Falls, has awarded the contract for the construction of a 2-story, 105x375-ft. factory, to the Lackawanna Bridge Co., Bell and Abby Sts. Estimated cost, $300,000.

FORESTPORT—The Forestport Pulp Mills, Inc., plans to construct additions and make improvements here. Estimated cost, $50,000.

HINCKLEY—The Otsego Falls Paper & Pulp Co. of Fulton has purchased the plant and equipment of the Hinckley Fibre Co. here, and plans to construct a new addition and make improvements at same. Estimated cost, from $250,000 to $300,000. H. L. Paddock, Fulton, pres.

LONG ISLAND CITY—The Drug Products Co., 48 West 4th St., has awarded the contract for the construction of a factory and laboratory on Jackson Ave. and Pierson St., to the Gretsch Eng. Co., 103 Park Ave., New York City. Estimated cost, $175,000.

MASSENA—The Aluminum Co. of America plans to construct additions to its present plant here. Estimated cost, $250,000.

NEW YORK—M. B. Schmidt, archt., 14 East 46th St., will soon award the contract for the construction of a 4-story, 50x50-ft. paint factory on West 58th St., for William Zinsser, West 59th St. Estimated cost, $50,000.

TONAWANDA—The Economy Pulp Mfg. Co. of Buffalo has purchased the vinegar works here and plans to refit and remodel it for a pulp plant. Estimated cost, $50,000.

WELLSVILLE—The village has voted $15,000 bonds to construct an additional filter unit, etc.

Ohio

ALLIANCE—The Bd. Educ. will receive bids until June 7 for the construction of a 3-story, 114x172-ft. school building. A chemical laboratory will be installed in same. Estimated cost, $500,000.

ASHTABULA—Robert Locke, pres., will soon award the contract for the construction of a 1-story, 110x600-ft. sheet steel mill on the State Rd., for the Ashtabula Steel Co. Estimated cost, $350,000.

CLEVELAND—The De Mooy Palmer Co., 65th St. and Sweeney Ave., has awarded the contract for the construction of a 1-story, 50x150-ft. foundry to Ford & Sons Co., foot of East 40th St. Estimated cost, $25,000.

CLEVELAND—The Natl. Malleable Castings Co., Woodhill Rd. and Quincy Ave., has awarded the contract for the construction of a 1-story, 100x500-ft. kiln on Woodhill Rd., to the Amer. Tunnel Co., New Castle, Pa. Estimated cost, $250,000.

COLUMBUS—The Climax Rubber Co., Citizens Bank Bldg., will build a 2-story, 140x190-ft. rubber plant on West Goodale St. Plans include a power plant and office building. Work will be done by day labor. Noted April 21.

EATON—The Bd. of Pub. Affairs will receive bids until June 23 for the construction of a filtration plant, etc. Estimated cost, $27,000. J. H. Beatty, clk.

EUCLID—The village plans to build a sewage disposal plant including settling tanks, screen buildings, etc. Estimated cost, $150,000. G. B. Gascoigne, 618 City Hall, Cleveland, engr.

IRONTON—The Fearon Lumber & Veneer Co. is in the market for dry kiln equipment including seventy-five 6-in. or 6½-in. roller-bearing dry kiln trucks (used preferred).

Rhode Island

WOONSOCKET—The Amer. Wringer Co., 91 Social St., will soon award the contract for the construction of three buildings, including a 1-story, 80x100-ft. dry kiln and a 1-story, 60x186-ft. mechanical roll building, etc. Estimated cost, $100,000. Cooley & Marvin Co., 711 Tremont Bldg., Boston, Mass., engrs.

Texas

PALACIAS—The Palacias Sewer Co. will soon receive bids for the construction of a sewage disposal plant. Estimated cost, $35,000.

VERNON—The Victor Pipe Line & Refining Co., Dixon Bldg., plans to build a 1-story, 2,000-bbl. oil refinery, here. Estimated cost, $150,000. J. W. Hudson, dir.

Virginia

BEDFORD—The city has awarded the contract for the construction of a filter plant, storage reservoir, steel tower and tank, etc., to Diehl & Vance, Virginia-Carolina Bldg., Norfolk.

Washington

MICA—The Amer. Firebrick Co. will double the capacity of its plant by building a hotel and kilns. Work will be done by day labor.

WENATCHEE—The city is having plans prepared for the construction of a complete water filtration plant with a daily capacity of 2,500,000 to 3,000,000 gal. Estimated cost, $50,000. M. Zahren, engr.

Wisconsin

GALESVILLE—The Galesville Canning Co., Onalaska, has awarded the contract for the construction of four 1- and 2-story cannery buildings, to J. E. Wallace, La Crosse. Estimated cost, $100,000.

KENOSHA—The Bd. Educ. plans to build a high school. A chemical laboratory will be installed in same. Estimated cost, $500,000.

MILWAUKEE—The Bernert Mfg. Co., 489 12th St., is having preliminary plans prepared for the construction of a 60x120-ft. foundry. Foundry equipment will be installed in same. Joseph Glaser, 713 Caswell Block, archt. Noted May 4.

British Columbia

VANCOUVER—The Vancouver Gas Co., 425 Carroll St., has awarded the contract for the construction of a retort house plant of special units and machinery, to the Wists Gas Improvement Co., Manchester, England. Estimated cost, $340,000.

VICTORIA—The Victoria Gas Co., 1016 Langley St., has awarded the contract for the construction of a retort house plant of special units and machinery, to the Wists Gas Improvement Co., Manchester, England. Estimated cost, $216,000.

Ontario

BRAMPTON—W. Treadgold, engr., is receiving prices on the supply and delivery of two 8x16-ft. horizontal, mechanical pressure filters, etc., for the city. Estimated cost, $35,000.

ELK LAKE—The Matachewan Gold Mines, Ltd., plans to install a 100-ton crushing mill. Estimated cost, $50,000. W. H. Seaman, mgr.

GANANOQUE—The Eastern Ontario Milk Products Co. plans to construct a factory here. Estimated cost, $150,000. Address L. P. Sherwood, Central Chambers, Ottawa.

LONDON—The Bd. Educ. plans to build a high school on Waterloo St. A chemical laboratory will be installed in same. Estimated cost, $500,000. A. A. Langford, chn. L. E. Carrothers, archt.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold a regular meeting June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its twelfth semi-annual meeting as follows: June 28 and 29 will be spent in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the affiliated societies.

THE AMERICAN SOCIETY OF HEATING AND VENTILATING ENGINEERS will meet in St. Louis May 27 to 29.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Collection Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE CANADIAN INDUSTRIAL CONGRESS will be held at Victoria, B. C., June 2 to 10.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NEW JERSEY CHEMICAL SOCIETY will hold a regular meeting and ladies' day Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

Industrial Notes

THE NEW JERSEY ZINC CO., New York City, has added to its staff Bushnell Bigelow as assistant general sales manager and Walter I. Hess as manager of Eastern sales.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., announces that L. Brandenburger, of Salt Lake City, who was formerly located in the Walker Bank Bldg., has taken larger quarters at 59 West Broadway.

THE ELYRIA ENAMELED PRODUCTS CO., Elyria, Ohio, has moved its New York office from the Architects Bldg., to 103 Park Ave.

THE DIAMOND POWER SPECIALTY CO., Detroit, Mich., received during January, February and March, 1920, orders to equip a total of 635,200 hp. of boilers and economizers with mechanical soot blowers.

THE GORDON DRYER CORP. announces the removal of its New York offices, formerly located at 39 Cortlandt St., to 1 Liberty St. Announcement is also made of the removal of its Bush Terminal experimental and research laboratory to Providence, R. I., where the main works and offices are located.

EDWARDS F. WILSON, formerly chief chemist and fuel engineer of the Westmoreland Coal Co., at Irwin, Pa., has opened a consulting office and testing laboratory at 222 South Third St., Philadelphia, where he will specialize in fuels, iron and steel, industrial water, etc., reopening in this connection the business of the Iron-Masters' Laboratory, of which he was formerly in charge.

THE ATMOSPHERIC CONDITIONING CORP., Philadelphia, Pa., announces the appointment of Benjamin Nelson as Western manager, with offices at 1301 Monadnock Block, Chicago, Ill.

THE WELLMAN SEAVER-MORGAN CO., Cleveland, Ohio, has elected John A. Penton, president of the Penton Publishing Co., a director to fill the vacancy on the board caused by the death of Samuel T. Wellman.

GUY FRIDLEY, formerly in charge of the fertilizer department of the Davidson Commission Co., Chicago, Ill., is now president and general manager of the Fridley Commission Co., Inc., Chicago, which company both sells and buys fertilizer materials.

R. A. BROWN, president of the Alabama State Fair Association and president of the Chamber of Commerce, Birmingham, Ala., has been elected president of the Steel Cities Chemical Co., Birmingham, Ala., to build the Lay Culpeper plant.

WELLS, BRACKMAN & COLE is a new firm of architects and engineers that has been formed at Detroit, with James R. Wells president, Donald Cole vice-president and Harry C. Beckwith secretary-treasurer. The offices of the new firm will be located at 531 McKerchy Bldg., Detroit.

THE CAMPBELL GLASS & PAINT CO. and the Glidden Varnish Co. have established a branch office in Oklahoma City at 15 N. Lee St. Parker Spencer will be in charge of the distribution of products in the territory.

THE EATON MFG. CO., of Omaha, Neb., has established a branch sales office at 132 West Second St., Oklahoma City, in charge of J. S. Kotva.

THE O'REILLY-LEEWRIGHT CO. has established a manufacturing plant at Oklahoma City for the production of paint and roofing compounds.

THE NATIONAL BUREAU OF WHOLESALE LUMBER DISTRIBUTORS will move its headquarters from Washington, D. C., to Chicago, locating in the Arcade Bldg., 615 South Michigan Ave. L. R. Putnam, formerly with the Southern Pine Assn., has been retained by the new association as executive secretary.

THE SERVICE MACHINE CORP. has moved its plant to 449-51 E. Ohio St., Chicago, Ill.

THE MERCANTILE CHEMICAL CO. has established a new plant at 2955 W. 47th St., Chicago, Ill.

THE RELIANCE WEIGHING MACHINE CO., maker of automatic recording weighing machinery, has purchased the business of the National Automatic Scale Co. New quarters for the organization have been provided in the Mallers Bldg., Chicago, and the company's factory in the central manufacturing district of Chicago will be greatly enlarged.

THE MONROE STEEL CASTINGS CO., Monroe, Mich., has sold its capital stock and physical assets to Detroit interests. The capacity of the plant will be immediately increased for the production of a general line of steel castings. Carl Clark is president and general manager of the new company.

THE METAL & THERMIT CORP., New York, announces the appointment of Charles F. Lederer in the rail welding department.

THE GENERAL BRIQUETTE CO., New York City, announces that Henry Schoch, sales engineer, has been elected vice-president of the Nukol Fuel Co., of Ontario, Canada. The Nukol Fuel Co. is manufacturing "Nukol," an anthracite briquet, for the Ontario market.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa., has appointed A. E. Hitchnie, formerly manager mining section, industrial department, to the position of assistant to the manager, industrial department, in charge of mining and chemical industries.

THE SCHAFFER ENGINEERING & EQUIPMENT CO., Pittsburgh, Pa., in order to provide for the expansion of its business and to obtain plant facilities, has sold a large block of its capital stock to the Fawcus Machine Co. The Schaffer Company's processes, engineering achievements and line of machines include pedometers, hydrators, coal injectors and screens. The Fawcus Machine Co., manufacturer of gears and special types of machinery, with large plants at Pittsburgh and Ford City, will build all machinery required. The new officers and directors of the Schaffer Engineering & Equipment Co. are: A. F. Cocke, president and general manager; J. C. Schaffer, vice-president; Eliot A. Kebler, vice-president; A. A. Alles, Jr., treasurer, and Walter Crew, secretary.

THE PAGE STEEL & WIRE CO. announces the removal of its offices to the offices of the American Chain Co., with which it has consolidated, in the Grand Central Terminal, New York.

THE GENERAL COMBUSTION CO., Chicago, Ill., announces the appointment of George R. Brandon, formerly engaged in engineering and sales of foundry equipment and cranes, as district representative and sales engineer. The General Combustion Co. manufactures "Conjax" furnaces for all industrial purposes. Mr. Brandon's headquarters will be 342 Monadnock Bldg., Chicago.

S. S. HEPWORTH CO., New York City, has appointed C. A. Oland general manager and E. F. Babbitt assistant manager, effective June 1, 1920.

THE WALTER E. LUMMUS CO., Boston, Mass., has appointed Raymond R. Collins, formerly head of the construction department, as sales manager.

HANFF-METZGER, INC., general advertising agent, New York, has appointed Francis Juraschek head of its technical department.

THE IMPROVED EQUIPMENT CO. announces the removal of its offices to 24 State St., New York City, on May 1, 1920.

THE WORTHINGTON PUMP & MACHINERY CORP., New York, announces that in addition to its lines of hydraulic machinery it can furnish improved water-power machinery of all capacities for low, medium and high head service, including oil pressure system, water wheel governors and other auxiliaries. It is equipped to produce hydraulic turbines, and an experienced staff has been secured to take care of this department.

THE JOSEPH DIXON CRUCIBLE CO., Jersey City, N. J., announces that George E. Long, senior vice-president, is retiring from that office, but will continue as a member of the board of directors.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, reports a repeat order for a 1½-ton Greaves-Etchells furnace from Charles Bertolus, St. Etienne, France; a new order for a G-E ½-ton electric furnace for A. Hamilton & Son, Cardiff, for the manufacture of castings; and the closing of a contract with the Emery Steel Co., Baltimore, Md., for an electric furnace of new design for annealing steel castings. Announcement is also made of an electrode cooling ring and economizer, which effectively prevents the ignition of the hot gases escaping from the furnace roof. The net result of this is considerable saving in the wear of the furnace roof, and also great economy in the amount of electrodes consumed.

Manufacturers' Catalogs

THE STANDARD ELECTRIC & ELEVATOR CO., Baltimore, Md., has issued a very attractive 80-page catalog entitled "Modernizing America's Industries." It suggests methods for industrial modernization and gives facts that should be of value to officials, managers, production engineers and maintenance engineers. Many illustrations are given, among which are some of the officials of the company, interior of several departments, together with their products, and descriptive matter.

THE READING VALVE FITTINGS CO., Reading, Pa., has issued a catalog of steel and iron flanged and screwed fittings and flanges.

THE W. S. ROCKWELL CO., New York, announces six new publications. No. 209 is entitled "Automatic Hardening and Tempering Furnaces"; No. 210, "Worth-While Facts for Users of Blast Gates"; No. 211, "Saw-Hardening Furnace"; No. 212, "Spring-Fitting Furnaces"; No. 213, "Drop Forging Equipment and Layout," and No. 216, "Factors to Be Considered in Heating and Cooling Steel." The last publication mentioned has been written for the benefit of the man in charge of shop operations, and attempts to express the principles governing heat-treatment work.

THE STEERE ENGINEERING CO., Detroit, Mich., announces three pamphlets, on electrically welded steel pipe and fittings, cooling coils, and welded steel piping.

THE HIRES TURNER GLASS CO., Philadelphia, Pa., calls attention to a very attractive catalog on "Glass for Every Industry." This catalog, which deals with "Lighthouse" quality glass and accessories, is published in four languages: English, Spanish, French and Portuguese, and has been prepared for the convenience and information of purchasers. Complete information and illustrations are given for glass for building and other accessory purposes, including plate glass, window glass, wire glass, rolled glass, "Saftee" glass, etc.

THE NEW YORK TESTING LABORATORIES, New York City, is distributing a four-page folder on Metallurgical Service.

THE STAR BRASS WORKS, Chicago, now has ready for distribution a 24-page bulletin, 4-A, covering spray cooling equipment for the cooling of water from steam and ammonia condensers. This literature gives illustrations of many recent installations, in addition to information respecting spray cooling systems for power and industrial plants.

THE DURIRON CASTINGS CO., Dayton, Ohio, announces Bulletin 111, on comparative tests on vitrified tile pipe, lead pipe and Duriron pipe, conducted by the testing laboratories of the school of engineering of Columbia University, November, 1919.

WILLIAM GAERTNER & CO., Chicago, Ill., calls attention to two catalogs. Catalog M illustrates and describes instruments of precision, such as measuring microscopes, comparators, cathetometers, etc. Catalog L, on optical instruments, illustrates and describes spectrometers, spectroscopes, optical benches, photometers, etc.

THE WHEELER CONDESER & ENGINEERING CO., Carteret, N. J., has published the 1920 edition of Steam Tables for Condenser Work. The book gives the properties of saturated steam from 29.8-in. vacuum to atmospheric pressure in increments of tenths of an inch. The vacuum in inches of mercury is referred to a 30-in. barometer. This method is of course superior to the old method of giving absolute pressures in pounds per square inch, since it is customary to read vacuum in inches of mercury. A complete table is also given of the properties of saturated steam above atmospheric pressure. The pressures below atmosphere have been especially calculated for this book by Prof. Marks.

THE BRIDGEPORT BRASS CO., Bridgeport, Conn., has prepared a book on "Brass." The book, which is most excellently printed and illustrated, describes in detail the art of brass making, dating back hundreds of years, leading up to the most modern practices as in use in the Bridgeport Brass Co.'s plant, including the electric casting shop. The important steps in the making of tubes, sheet, rods and wire are also shown. Following a full description of the modern methods of manufacture, which includes some details of methods not commonly found in print, the properties of brass are briefly noted as they are affected by composition, cold-working and heat treatment. This section should assist engineers in drawing specifications. In the compilation of this work the company has deviated from fixed conventions and traditions of the brass industry by making an open book of the practices and processes of brass making. It is extremely well written, and there are few even who have been associated with the brass industry for years who would not find it a valuable addition to their library.

THE METAL & THERMIT CORP., New York, has issued a third and revised edition of its pamphlet entitled "Laboratory Experiments With the Thermit Process of Welding." This pamphlet is useful as a guide for acquainting students with the substance, characteristics and results of the Thermit reaction. The pamphlet illustrates and describes various experiments which are intended to show the speed of the reaction, the heat produced thereby and the effects obtained by the superheated liquid slag and the superheated liquid steel.

WILLIAM R. PERRIN & CO., Chicago, Ill., calls attention to a new pamphlet on filter presses. This four-page pamphlet illustrates and describes filter presses of various designs, gives a table of sizes, working pressure, weights, etc., filter presses with square plate and frames, and a separate sheet is inclosed on recessed filter plates and flat filter plates and extension frames.

NATIONAL ENGINEERING CO., Chicago, Ill., has published a catalog on the National Screen Separator, which contains eight pages of illustrations and descriptive matter.

BAUSCH & LOMB OPTICAL CO., Rochester, N. Y., calls attention to an attractive 64-page catalog on Photographic Lenses. Many interesting illustrations are given, together with descriptive matter.

EDWARD R. LADEW CO., INC., Glen Cove, N. Y.: "Ladew Leathers" is the title of a 56-page book which illustrates and describes different kinds of belts, with price lists, automobile leathers, whole leather, leather packings, pump leathers, leather shafting rings, rub roll aprons, mill strapping, etc.

THE BLAW-KNOX CO., Pittsburgh, Pa., started in April, 1920, the monthly publication of *Blaw-Knox Life*. The May issue is out now and both issues are very interesting.

THE PFAUDLER CO., Rochester, N. Y., has issued a 32-page booklet, Bulletin C-5, on glass enameled steel equipment for the chemical industries which is designed to give a comprehensive idea of the application of glass enameled steel equipment and apparatus to the manufacture and handling of corrosive and sensitive liquids. Each illustration shows either a standard type or a characteristic feature.

ALLDAYS & ONIONS, LTD., Birmingham, England, is issuing a 4-page pamphlet on Oil-Firing for Boilers, which deals with its patent oil burners, giving diagrams and full particulars of a number of characteristic conversions to liquid fuel.

THE GRISCOM-RUSSELL CO., New York, is issuing Bulletin No. 902, on Multi-whirl Cooler, which is for the cooling of oil used in the lubrication of turbine bearings, reduction gears or quenching oil in the heat treating of steel. In either case the oil is constantly circulated through the cooler, thus maintaining the oil at a constant temperature and permitting the continued use of the original quantity of oil and its maintenance at the proper viscosity for efficient results. The apparatus takes its name from the whirling path of the oil, which path is accomplished by the use of the helical baffle which directs the oil in its flow without appreciably retarding its progress. This baffle also serves to bring the oil into intimate contact with the cooling surface and it insures a high rate of heat transfer. The shell is of cast iron and the tubes of seamless drawn brass or copper, expanded into a fixed tube plate at one end and into a floating head at the other which latter permits expansion and contraction without strain on the tube joints. The cooling of quenching oil insures maintenance of the quenching bath at a fixed temperature and also permits the use of cheaper grade oil.

THE DU PONT CHEMICAL CO., Wilmington, Del., is distributing a booklet entitled "The Way to Increased Production," which gives some facts in regard to the company's gigantic sale of war surplus material. Although the book is by no means complete as an inventory of the matrial on hand, it nevertheless does give an idea of the mountains of supplies handled by this organization. The du Pont Chemical Co. took over the supplies and equipment of the war plants of the du Pont Co., and some idea of the magnitude of the work involved can be had when it is considered that the inventories of the various plants developed something more than 70,000 cards, consisting of from one to a dozen separate items. In all, it was found that there were more than 500,000 different items of material and equipment available for sale, and these include an enormous range of articles in daily use, covering a little of everything, from pins to platinum. General machinery of all kinds is on hand, and there is also special machinery built for manufacturing purposes peculiar to the powder business but which can, in many instances, be used in other industries with slight changes. The du Pont Chemical Co. is now engaged in a national advertising campaign to sell these materials and the stocks are moving fast. The pamphlet ought to be a valuable handbook for buyers in every line in the present state of the market.

EIMER & AMEND, New York City, has issued two new bulletins. Bulletin No. 268 is entitled "The Hortvet Cryoscope," which is of importance in the testing of milk. Bulletin 269 is entitled "American Rotary Vacuum Pumps and the MacLeod Vacuum Gauge."

NICKLE ENGINEERING WORKS, Saginaw, Mich., announces a new bulletin entitled "Agitator Driving Yokes," a standard power transmission device—made in several styles and sizes—for driving agitator or stirrer shafts in chemical tanks and kettles. Illustrations show how these driving yokes are mounted on both open and closed containers. A table of dimensions, convenient for draftsmen, is also given.

H. R. WAHL & CO., Chicago, Ill., has published a catalog describing a new type of machine, adapted to such work as dewatering, classifying and washing ores or other granular material, known as the Wahl dewatering machine.

THE JOINTLESS FIRE BRICK CO., Chicago, Ill., is distributing a booklet entitled "General Information for Installing Plibrico Jointless Fire Brick."

THE ESTERLINE CO., Indianapolis, Ind., in the *Esterline Graphic* treats the subject of Graphic Instruments in the Field of Transportation. The company says that many people think a curve drawing meter is a delicate, sensitive instrument which must be handled by an expert with the greatest care, but that the Esterline graphic instruments have given satisfactory service under the severe conditions as described in this pamphlet.

A Dollar for War, A Penny for Progress

APPROPRIATIONS for the fiscal year ending June 30, as given in the regular supply bills and three deficiency bills in Congress prior to that date, show the national budget to amount to about 5⅔ billion dollars, really a huge sum when most of us can remember the political hullabaloo raised by the first "Billion Dollar Congress." But the size of it, staggering as it is, is not so important as its distribution, as has been brought out very forcibly by Dr. ROSA of the Bureau of Standards.

He arranges the budget into groups. In the first is found expenditures on account of previous wars and our military establishment. Another group covers primary governmental functions—the executive, judicial and legislative. Next comes public works—rivers and harbors, buildings, reclamation and parks. A fourth includes research, educational and developmental activities, such as in the Agricultural Department, Geological Survey, Bureau of Standards and Bureau of Mines, Library of Congress, Public Health and Vital Statistics. Last comes self-supporting activities such as Post Office, Patent Office and Land Office. Tabulating:

Wars	$5,280,000,000	or	93 per cent
League of Nations	0		
Governing	181,000,000	or	3 per cent
Public Works	168,000,000	or	3 per cent
Development	57,000,000	or	1 per cent
Self-Supporting Offices.	balance		
Total	$5,686,000,000	or	100 per cent

For destruction 5,280 millions and for development 57 millions! "A dollar for war, a penny for progress"—a slogan for 1920 perhaps worthy of a place alongside PINCKNEY'S "Millions for defence, not a cent for tribute!" Rather than increase the burden of taxation, the Congress is unable to afford an expenditure of more than 9 cents per capita on the Bureaus of Plant and Animal Industry, 2½ cents on the Bureau of Mines and Geological Survey, 3½ cents on the Bureaus of Standards, Fisheries and Foreign and Domestic Commerce, and the same amount on Public Health Service. Particularly adequate appears an expenditure for education of 7 cents per capita by a national government, one million of whose drafted soldiers could not read and write!

It requires little argument to convince technical engineers that research pays. It requires as little to get an admission from any American that education pays. The moot point is whether the United States Government should finance the research, or how far it should go in supporting education. The determining answer seems to be that it can and ought to proceed energetically along those lines which are basic or fundamental—applicable to many activities of various nature and differing magnitude. The individual farmer cannot of himself experimentally determine the exact advantage of a potash fertilization—his state agricultural school is more likely to be working along those lines if he happens to live in the South. If he lives in the North he will naturally turn to the national Department of Agriculture for an unbiased opinion on his problem.

Similarly in metallurgy and chemistry. Who is interested in collecting data on little-known natural resources with only a remote chance of quick financial reward unless it is the Bureau of Mines? Could one get a better opinion on the proper pyrometer for a certain problem from Dr. BURGESS or from an instrument maker specializing in thermocouples? Where does the chemist go when he wants a certificate of accuracy for a fine thermometer?

Illustrations might be endlessly multiplied to little point, since each individual reader is familiar with one or more of them. Dr. ROSA presents an almost unanswerable argument to the lay mind, however, which ought to be widely used when occasion warrants. Starting from the premise that the Government should be constructive and helpful to the people and to business generally and without regard to condition or location in order to establish good relations, elevate business methods, increase efficiency and the general joy of living, it certainly seems that 1 per cent of its total expenses is a very small proportion in view of the economic value of the work. But even a considerable part of this miserable pittance is consumed by activities on behalf of the Government itself—in routine tests and investigations. Even here the Government would spend far less for its purchases if it spent more in standardizing and specifying those purchases and systematically testing the deliveries. Apart from the service the Government can render in educational work, all its scientific and developmental work develops wealth multiplied like fruit from seed. There is now required many times the revenue formerly needed; expenditures for development, however, lighten taxation by largely increasing the taxable wealth. It is as productive and profitable in peace as in war. It constitutes a standby reservoir of unsuspected potential possibilities.

Finally, if the reasons are not already sufficient, there remains the military reason. Who denies that Germany was so hard to beat because she was so well prepared technically? On our part, the development of our intellectual, moral and material resources was a thing consuming time, and costing many, many priceless lives, yet, as the event proved, more indispensable to final success than the initial equipment of armies and fleets. The conclusion is irresistible that a Government that pays great attention to education, research and industrial development is making the best preparation for possible wars in the future. It tends to prevent war, and so pays for itself twice over.

What will our children's judgment be of men who had nothing for a League of Nations, and but 1 per cent for construction?

Another Case Of Secrecy

THERE has just come to attention another instance of unreasonable and wholly unnecessary attempt at secrecy on the part of a certain prominent firm in the metallurgical industry in this country. This corporation has gone to the extreme in having all its plant equipment and machinery built in its own machine shops for the avowed purpose of preventing any outside interests from securing even a clue as to the methods and appliances used in its plants.

We much deplore any policy like this and do not hesitate to criticize the attitude of mind which gives rise to such methods. Under no circumstances can an industry expect to profit permanently by such policy. A free exchange of information and a very general knowledge of and interest in plant processes are the best possible means for encouragement of additional development of the art and industrial advancement of the manufacturing plants engaged within the field in question—indeed, within any line of activity.

No company can afford to take such a stand as this corporation in question. It is out of the question for any one company to know so much about a particular process, metallurgical, chemical, or what not, as to be unable to learn more if research and development are encouraged on all sides. Concentration of industry is desirable up to the point sufficient for best efficiency; but there is no reason for feeling that a reasonable measure of publicity is the occasion for undue competition. If any element of an industry cannot succeed despite a certain measure of competition, because of its greater skill of management or more rapid adaptation of science to the plant process, CHEMICAL & METALLURGICAL ENGINEERING is heartless enough to believe that it does not deserve to succeed. This narrow-minded metallurgical concern is making a success of its manufacturing operations; but we should much prefer to see this success by a frank, open policy rather than by the means which it apparently desires to use.

Chemistry Conquering Another Industry

THE fertilizer business has been very negligent of all branches of chemistry in times past, but we can be much encouraged to see that it is rapidly being convinced of the need for chemical control. One large manufacturer is quoted as saying recently, "Why, we have to analyze almost every shipment of phosphate rock which we receive these days." And the interest in the analysis is by no means confined to the phosphate, for with the present scarcity and high cost of the nitrogen and potash supplies it is increasingly necessary to make accurate determination of all the materials used and the products shipped.

In writing of the present fertilizer situation, Dr. WHITNEY well says that there is an active change going on at the present time converting a sort of "scavenger business" into a true chemical industry. This progress should be accelerated, too, for the urgency of the national food situation will place new burdens upon the fertilizer manufacturer which he will be ill prepared to bear without the best of support by all branches of the related sciences. Thorough knowledge of the materials and processes used will give added power to meet these new demands; and surely there is no more promising means for gaining this added knowledge than through full chemical control.

In this advance within the factory for the production of fertilizer a still larger need for investigation of methods of fertilizer use and application is co-existent. The possibilities of many fertilizer materials coming on the market in the form of practically pure chemicals must be taken into account by the agriculturist. If he can be supplied with the needed amounts of potash, phosphorus and nitrogen in usable form as pure salts, what is the farmer expected to do with them? Thus far the practical application of fertilizer to the soil has been based upon the supply of useful elements mixed with a bulky mass of much less, or in some cases no, fertilizing value. To change from this method the farmer must learn to use the salts in an entirely different way. It immediately is suggested that as all these salts are readily soluble they should be applied in solution. This is all well enough for some of the crops, and this plan might easily be adopted where correct sprinkling facilities are available, as is generally the case in the tobacco-growing districts. But the wheat or corn grower has no such equipment, and a new practice will therefore have to be introduced. It does seem, however, that the possibilities of such complete change as this are not at all out of the question, if we can supply these materials at prices that are attractive to the user.

Stop, Look, Listen, And Keep a-Looking

ONCE more the season of the year has rolled around when the seniors of college are graduated into freshmen of life. In the main they have been taught to listen attentively and absorb everything they have been told in a very credulous manner. The closer they have confined themselves to the details embodied in their courses and the more intensively they have imbedded these few facts in their memory, the greater has been their reward in grades and honors. However, in the school of life, other factors in addition to listening and concentrated attention control the attainment of success. The most important of these is zealous looking and believing better after seeing. Of course this must not be construed that before reaching sophomore requirements in the great world college our credulous freshman must turn into an incredulous, absolute Doubter. But he must have a sense of weights to attach to what he believes, which for want of a better word to embody the idea may for the present be called scruples. When he gets experienced in scruple determinations, he should be classed as a junior and in the interpretation of the weights he has no doubt qualified for the senior class of the school of life.

Now, the world college does not care much about the annual cycles and has no semesters, lecture periods or terms. A man may spend his life in the freshman class or he may ascend into the higher classes almost immediately upon matriculation. There are no flunks, but just promotions, and these only to whom they are due.

All of us unconsciously grade the men we meet day by day. As a personal example, making editorial calls upon men engaged in the industries with which this journal is concerned, after getting sufficiently acquainted, the most desired information is to get his scruples of belief on various topics, especially on those the journal

is printing relative to his field. If he says something to the effect that if all the articles are as full of bunk as such and such a one, which he happens to believe he is entitled to criticize adversely, he is at a loss to know whether to put his entire confidence in any of those articles with which he is only slightly familiar, he is immediately graded out of the freshman class. If he shows a degree of tolerance for the views of the author with whom he disagrees, he has passed through the sophomore class and if he can show better logic in his own channels of thought and not be a mere shallow advocate, he has certainly reached seniority.

This same idea may be expressed chemically and for those not mathematically inclined we will now substitute the salt content for the scruple. How much salt do you, Mr. READER, add as a condiment to the stuff with which you feed your brain? If you don't add any, it is probable that you have a poor mental digester and your brain is nothing more than a warehouse for the facts that someone else is generous enough to think out and store with you. If you are too liberal with your salt and add it in great quantity, it is likely that you have a pork barrel on your shoulders instead of a regular head. You'll need a soaking out or you'll wilt everything new and fresh that you touch.

The man who takes the time to listen and look certainly has the best chances for success. In reading technical literature, his attitude should be that of a listener in an audience of sixty or seventy thousand, several of whom have dared to speak out in meeting. If he has never contributed, he will probably not know how to interpret properly the spirit of the author. If he has contributed, he will stop, look and listen, and if the ideas conveyed in the article interest him, he will keep a-looking and develop them.

Chemistry Gone Wrong

WE LATELY saw a piece of silk that had an interesting history. As raw material there were sixteen ounces to the pound, but after washing this was reduced to twelve ounces. In order to avoid confusion by the higher mathematics of the silk industry, let us keep in mind this pound of raw silk that weighed, first sixteen ounces, and then twelve ounces. The twelve-ounce pound was passed through a bath of stannic chloride and afterward through another bath of sodium phosphate. These baths were repeated alternately a considerable number of times, after which the silk received a bath of aluminum sulphate to swell the fiber. Then back it went to the tin and the phosphate baths again, to charge the swollen fibers with more loading. Then it had treatment in another bath of silicate of sodium. After this it was dyed a fine rich black with logwood, which added more weight. The final treatment was with oil, to give it luster. The result was ninety-six ounces of beautiful black "silk," of which twelve ounces were and eighty-four ounces were not.

Just how long stockings that are made of this fabric will last is a subject for speculation, but the merchant that guarantees that the fibers are all silk and that the stockings contain no cotton is right as to the facts, although the truth may be strained in the exposition. He shows sound business judgment in refusing to accept the return of goods after they have been worn.

The Simple Life For Some Employers

IN THESE times of varied talk and opinions on the labor situation, such as befog the mind of the observer to the despair of any real decision, comes the clear-cut statement of WHITING WILLIAMS, who has spent seven months of investigation among the common laborers in many steel plants and coal mines throughout the country. His research has been made recently and consequently his opinions carry more weight than those of men formerly associated with the laboring class who have grown away from the viewpoint of the worker and become corpulent in purse and body from the general development of industry.

Mr. WILLIAMS says the average common laborer wants first a steady job; second, living conditions permitting full rest when off duty, and third, education in what the employer is trying to accomplish. Briefly and plainly, he requires "joy in his job." It would seem comparatively easy to bring about this condition for the laboring man if the employer has a touch of human nature in his make-up. Let the boss forego too much criticism, although it may be merited in many instances. Let him study his business to keep the supply of work uniform throughout the year, and lend every aid in improving housing and living conditions for his men.

The thing that strikes home forcibly, however, is that the laboring man must feel the importance of his part in the economic structure. The enthusiastic scientific management expert with a goal wherein each man handles only one small operation has carried things to a point where effort has become purely mechanical. The human factor and true craftsmanship have suffered. A large fraction of a man's life is lived at work, and if pleasure cannot be found therein, he becomes useless alike to himself and employer, with a mind filled with bitter resistance.

The situation calls for human sympathy without patronage on the part of the employer, and if he cannot operate on this basis with profit, it is far better that his factory be turned over to someone else or the doors closed.

Fate of The Dye Bill

THE dye bill (H. R. 8,078) is breathing heavily but is not dead yet. Senator THOMAS of Colorado talked against it for nearly a week. Other champions of liberty who lend their voices to importers or to those textile manufacturers who would rather get their dyes cheaply than have their country independent have announced their intention to "speak at length" against it. This indicates an organized filibuster, but it also indicates that if it comes to a vote, it will pass. Much depends on whether Congress adjourns or takes a recess.

It is reported that the European Allied governments have decided to stop supervision of the German dye industry and have consented that Germany may supply as much of the world's dye needs as she can for the next five years. It is also said that the dye industries of England and other Allied countries have failed to keep pace with the development in the United States and they fear that the United States might get as definite a lead as Germany had before. The sales of American-made dyes to Latin America alone in 1919 totaled $3,100,000. And this, according to a bulletin of the Chemical Foundation, is merely the beginning.

Readers' Views and Comments

Microstructure of Iron and Mild Steel at High Temperatures

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest the editorial on "Extrusion or Diffusion" in the April 28, 1920, issue of CHEMICAL & METALLURGICAL ENGINEERING. I am inclined to believe that the casual reader will credit Mr. Scott and myself with much more than the results of our work will justify. We did not intend, as the reader of this article may be inclined to believe, to discredit Dr. Howe's general theory. The evidence he has is too strong to be lightly brushed aside. We did wish to show, however, that in the case with which we were dealing, i.e., steel heated for a considerable period at high temperature and in vacuo, the conditions which then prevail offset any such result that Dr. Howe's theory requires. The reference made to Dr. Howe is to a particular application which he made of his theory in explaining the apparent decarburization of specimens used for thermal analysis under the same conditions as our specimens were heated and not to the theory in general. The conditions which prevail in an enclosed internal cavity are quite different from those at the outer surface of a specimen heated in vacuo; many of Dr. Howe's best illustrations are of specimens showing the condition at the surface of internal cavities.

Washington, D. C. HENRY S. RAWDON.

What Does the General Electric Get Out of It?

To the Editor of Chemical & Metallurgical Engineering

SIR:—One night last week as I sat in the smoking room of a sleeping car there came in, first an elderly man, well preserved and apparently prosperous, who turned out to be the principal stockholder in a zinc company. Then appeared a younger one, an engineer, returning home after installing some machinery in the West. We were the only occupants of that room that evening, and in time the old gentleman began to talk. He started in with such a tirade against the Government that his critical faculties became unusually sensitized, and, as he liked to hear himself speak, he soon developed his art to cover a larger field. His animus against President Wilson seemed to have its origin in the fact that he had been a college professor as well as college president, and this led to an expression of keen distress that we have become no less than a professor-ridden people.

"They're all tarred with the same stick," he exclaimed, "and the trouble is catching. Now it's cropping out in industry. Wherever you go they want some damned professor to butt in. I got no use for 'em. One manufacturer after another is beginning to blow about his old labbatory and a lot of overhead charges that increase the cost of everything. First it was the General Electric Co. and now the Westinghouse and a lot of other little concerns are about as bad; but I got it in for the General Electric because I hold that they started it. They make good machinery—and so do the others—but whenever I buy anything from them I got to pay for their old labbatory when I settle the bill. Either they know their business, or they don't, and if they don't why can't they get some practical man to teach 'em? Who's this Dr. Whitney of the General Electric that they make such a fuss over? Some big college just gave him a gold medal—because he hires a lot of their professors to work for him, I suppose."

"Ever meet him?" asked the engineer.

"No; an' I don't want to," replied the man of zinc. "I bet he couldn't sell a ton of spelter if he took all day at it! And I'd ruther have a good gang of smeltermen with a reliable foreman over them to run my plant than all the Whitneys in the world. As for that fella Langmore [he persisted in calling him Langmore, so he probably was not of Scotch descent], he sure does make me tired. He goes down to Washington and talks by the hour to a lot of professors, and even they can't understand him! What's all this piffle got to do with making machinery anyway? Ain't he supposed to work for the company?"

"Well," remarked the engineer, "they seem to think it pays. You know, they made tungsten ductile, and that improved the electric light service. There was something worth while, wasn't there?"

"Say, every time anybody invents something they give the labbatory credit for it. I'll bet dollars to doughnuts some practical man did the inventing."

"I believe Langmuir had a hand in it," suggested the engineer.

"Aw, don't talk to me about Langmore; he's the worst of the lot. All he done, I'll bet, was to come around and bless it after it was invented. It's like the minister that baptizes a baby and then thinks it's his. He's no more practical than a college professor. He goes down to Washington, as I said, and makes a great hullabaloo over particles that are so small they ain't got no size to 'em. Then him and all the other roosters crow over it. It's nothin' but a lot of damned showin' off; that's all it is!"

"But," remonstrated the engineer, "it seems to be a step toward the better understanding of the phenomenon of light, and if we could only master that it might lead the way eventually to the discovery of a light motor. That would be something practical, wouldn't it?"

"Practical your grandmother! It's tommyrot. Thomas A. Edison invented the electric light. I'll admit that. These other fellas is jealous, and they're tryin' to pull themselves up by their bootstraps. That idea of a light motor is just about the worst I ever heard. Right in line with perpetual motion! Look here; it takes power to make light, but you can't get power from light. That's as bad as runnin' down hill to climb up!"

"Well, it's only the fossil energy of the sun we use when we burn coal, as Prof. Cimician said. It would be more economical to get it direct. That stands to reason, doesn't it?"

"I don't doubt it stands to the reason of this Prof. Shimmy, or whatever his name is, but you know as well as I do that it ain't practical. You might as well use windmills."

"I've often thought we might use windmills more than we do. Some day we may have sense enough to come back to them. But let's come down to something more familiar. Take the smelting of zinc, for instance. Doesn't that need research?"

"Now I think I know what I'm talking about when it comes to zinc, and I tell you it don't need research or any other monkeyshines to smelt it. *We know how to do it,* and have since your granddaddy was your age. You just put that in your pipe and smoke it!"

"Yes, but the furnaces are very small, the design is antiquated, the physical chemistry of the reactions is hardly studied, and the waste of heat in smelting zinc is out of all reason compared with smelting copper or iron. Wouldn't it be worth while to cut down the cost by gleaning some more knowledge of the subject and making practical applications of it?"

"It's easy to see," the old gentleman retorted, "that you don't know anything about the zinc business. We install the best and most economical furnaces that can be designed at a point where fuel is cheapest. That's what experience teaches. That is the practical fact, and it is not theory. No, sir; all that's needed in the zinc business is to keep up the price of spelter. Then we'll make you all the zinc you want. I'm going to bed. Good-night."

And to bed he went. But somehow I felt drawn to that engineer. I asked him to stay until I returned with my satchel, to which he agreed. In it I had a little legacy from a dear aunt who had often been a source of inspiration to me, but who has passed from us. I refer to Mrs. Ethel L. Cohaul. I shared my legacy with him. MARTIN SEYT.

Spark Coil for Explosion Pipettes

To the Editor of Chemical & Metallurgical Engineering

SIR:—In these days of the high cost of chemical equipment any substitution that can be made in the interest of economy which does not result in impairing efficiency is apt to receive a hearty welcome. Doubtless the following idea has occurred to many other chemists, but as I have not yet seen it in print I hope that some others will find the substitute to work as well as I did.

Some time ago the writer had occasion to direct some work involving a number of analyses of combustible gases. A gas analysis apparatus of the Steel Corporation type was available, but it was impossible to get a spark coil for it without some delay, and some sort of substitute must be sought.

A Ford spark coil proved the solution, and, needless to say, it could be purchased at once. These coils will give a spark of at least $\frac{1}{4}$ in. under the pressure in the cylinder of the car at the moment of explosion and at atmospheric pressure the spark will be about $\frac{3}{4}$ in. long —plenty long enough for this sort of work. We found two dry cells adequate for the primary current.

The only adjustment required is some sort of a clip to make contact with the disk on the side of the coil, and various ways in which this may be done will suggest themselves to the reader. As simple a way as any is to fasten a piece of spring steel or of brass across the disk with screws in the wood casing. This clip will hold the leads in contact with the terminal. This type of apparatus, according to our experience, is just as satisfactory as any Ruhmkorff induction coil and considerably cheaper. GEORGE S. TAYLOR.

Holyoke, Mass.

British Chemical Industry

(FROM OUR LONDON CORRESPONDENT)

London, May 7, 1920.

THE question of wages of workers in chemical industries referred to in my last article[1] has been settled for the time being, the Chemical Industrial Council having conceded an advance of about $2 per week plus 12½ per cent. The negotiations were prolonged and difficult owing to the attitude of a small section of extremists among the workers. Fortunately for the industry, the manufacturers' representatives possessed a lengthy and intimate knowledge of labor and in some cases were specially released from highly technical and executive appointments for the good of the industry as a whole. Although there is some hope that there will be a peaceful interval, the situation is really dominated by the activities of other trades unions, which are displaying considerable rivalry in securing the best possible terms for their members, with the result that a concession to any one union immediately brings in its train, irrespective of existing agreements, further demands from others whose jealousy and cupidity have thus been aroused. It is felt that unless industry as a whole combines to put a stop to this procedure, wages and prices will rise to such an extent as to render something in the nature of a miniature revolution inevitable, and it is small comfort that conditions in the United States and elsewhere are shaping in a similar manner.

"CHEMICAL TRADE YEAR BOOK"

This buyer's guide, which is a descendant of the "Trade Directory" last published by the *Chemical Trade Journal* in 1911, has just been issued at the price of 10s. by Bandon & Morris, of 17 Red Lion Passage, London, W. C., 1. In conjunction with the official directory of the Association of British Chemical Manufacturers, it will no doubt be of service to American merchants and manufacturers, although it cannot be described as either representative or complete. The Directory of the Association of British Chemical Manufacturers is obviously issued solely in the interests of its members, while the "Chemical Trade Year Book" not unnaturally consists essentially of those firms that have paid for advertising space. To be really complete and of value, such publications should be more on the lines of the American "Green Buyers' Guide" or the "Chemical Engineering Catalog," the former of which is particularly comprehensive and complete and is, moreover, issued free of charge. In addition, many of the firms quoted are often not the actual manufacturers or agents, but are acting as "ghosts" to others. It is hoped that this note will be of some service to American firms that may have occasion to consult such directories.

MR. BARTON BOOMS THE CLAUDE PROCESS

Evidently as a counter-blast to the official announcement of the acquisition of the government synthetic ammonia factory and interests by the Brunner Mond syndicate, the merits and prospects of the Claude process have just been advertised in the daily press.[2] It will be remembered that the Claude process consists essentially in the use of very high pressures of up to 1,000 atmospheres as against the 200 atmospheres previously employed, greatly increased yields and a substantial

[1] [illegible] MET. ENG., vol. 22, p. 837 [illegible]

[2] [illegible] MET. ENG., vol. 22, p. 481 [illegible]

reduction in the quantity of catalyst required being claimed. According to Mr. Barton's announcement, it is proposed to form a company known as Atmospheric Nitrogen & Ammonia Products, Ltd., with a capital of $10,000,000 and to erect a synthetic ammonia plant in Cumberland adjoining a large coke-oven plant owned by the same company. Interesting features are the announcement that the necessary supply of hydrogen will be obtained at a very cheap rate by special treatment of producer gas and that it is intended to place on the market, as a new type of fertilizer, ammonium chloride derived from synthetic ammonia, instead of ammonium sulphate, as in the case of other manufacturers in this branch of the nitrate field.

Status of Chemical Market

There has been practically no change in the chemical markets during the past month, but it cannot be stated that supplies are as yet approximating to the demand, particularly in regard to heavy chemicals and such items as formaldehyde, acetic acid and acetone. Mercury has also been a strong feature, but prices now show a downward tendency. As regards dyestuffs, there is still a shortage and great difficulty in making this up from Germany owing to the reduction in output due to shortage of coal in that country.

Future of Explosives Factories

The enormous cordite and explosives factory at Gretna will probably be continued and the original government factory at Waltham Abbey dismantled. In addition, it is proposed to use the ether-alcohol plant at Gretna for the purification of commercial methyl alcohol, and it is hoped that there will be an adequate demand for this from the dye, medicinal, photographic and other chemical industries, and also for ether, possibly in connection with the development of power alcohol. In regard to the latter, extensive new laboratories and a special staff of assistants are being provided for the government chemist and experiments are to be carried out on manufacture from vegetable substances and in regard to denaturing. The problem of finding peaceful uses for munitions factories is gradually being solved, and small arms, ammunition and fuse works are turning their attention to mechanical and other toys, clocks, sewing machines and the like, while Kynoch's large works at Arklow, in Ireland, are to be used for the manufacture of artificial manure in conjunction with the development of the Avoca copper mines. The new company is to have a capital of about $12,000,000.

Conference of Chemical Engineering Group

The third Conference of the Chemical Engineering Group dealt with labor-saving devices in chemical works, and while the papers presented were on the whole somewhat mediocre, they serve to focus attention upon the growing tendency of British manufacturers to eliminate manual labor wherever possible. An interesting point brought out during the discussion was the extensive use made in Germany of pneumatic conveying of materials and chemical substances, hot air being sometimes used with the object of simultaneously drying the material on its way from the hydro-extractors, etc., to the packing room. The subject of the next Conference in July at Newcastle is to be filtration, a subject which has not received the same careful attention in this country as in America, owing to the more restricted field for continuous and automatic appliances. It is, however, interesting to note that Vickers has recently undertaken the manufacture of the Gee type of centrifugal filtering and grading machine developed by Centrifugal Separators, Ltd., and that these machines are being extensively introduced in the china clay industry, in paint and composition works and even for the separation of sludge from sewage and the waste liquors and outfalls of chemical works. The machines not only filter but grade the precipitate, and their chief disadvantages appear to be the impossibility of washing the precipitate and discontinuous operation, difficulties which are likely to be overcome.

Colloidal Fuel

Another new company to exploit this process is a private one, the United Oil & Coal Corporation, Ltd., and it is rumored that L. C. Harvey, the European manager of the Fuller Engineering Co. of America, is a director. G. C. Calvert of the Metropolitan Laboratories, London, is stated to have patented similar mixtures under the name of "Colloil," while in regard to the application of these mixtures to railway work, experiments are being conducted by J. G. Robinson, chief engineer of the Great Central Railway Co. The latter have proved very successful, giving results fully equal to the use of bituminous coal, and it is stated that Mr. Robinson has developed a new type of burner, the dust and oil being mixed at the burner instead of previously, thus eliminating the use of a fixateur or peptizing agent.

Personal Notes

Sir Henry Birchenough has been appointed chairman of the British Dyestuffs Corporation in place of Lord Moulton, whose advanced age and heavy judicial work prevent him from continuing his work in this connection.

Prof. Henry Louis has been appointed foreign secretary of the Society of Chemical Industry in place of Dr. R. Messel, F.R.S., whose death last week is universally regretted.

Sir Richard Glazebrook is the first president of the new Institute of Physics, which has just been founded by the co-operation of the Faraday Society, the Optical Society and the Physical Society of London.

An Anglo-American amalgamation may be recorded, the British interest of the Monsanto Chemical Works, St. Louis, having amalgamated with R. Graesser, Ltd., of Ruabon, North Wales, under the style of the Graesser-Monsanto Chemical Works, Ltd.

Italy to Use Explosives in Agriculture

With a view to disposing of the surplus supply of explosives and at the same time benefiting agriculture, a series of experiments has been conducted by the Italian Ministry of War in connection with the breaking of ground. The results have been so satisfactory that it has now been determined to proceed to the practical use of explosives in agriculture on a large scale. In addition to preparing the land for cultivation, it is claimed that the use of certain explosives not only destroys parasites but also to a certain extent reduces the necessity for fertilization. It is proposed to establish in all districts of Italy demonstration fields where trials of the system which has been adopted will be carried out; such fields have already been created in Umbria, Puglie, Tuscany, and the liberated provinces. At the same time, the Ministry of War will turn over the large quantities of available explosives at favorable prices.

Scientific Control of the Filter Station—I

A Discussion on Clarification of Filtrate — Use of Lighter Filter Cloths Made of Open Woven Fabrics Advocated — Form of Solids in Cake Important — Method of Application and Use of Filter-Aids

By ARTHUR WRIGHT, M. E.

INDUSTRIAL filtration, as it has been so aptly put, "is a lowly art." Yet for so many years have rule-of-thumb methods obtained, it is consistent that with the introduction of the modern filter we are beginning to recognize that there are fundamental principles underlying the best operation of these filters. Filtration is no longer summed up in the old adage, "get a good hard cake," but comprises, in addition to clarification, the complete washing of the soluble from the deposited solids, the drying of the cake, thorough discharge of the cake so that the filter medium is maintained in a free filtering condition for recurring runs, and a consideration of pumps, filter cloth and other auxiliaries. It is only when these principles are understood and applied that the filter station reaches its true economy and efficiency.

Much effort has been made to acquaint superintendents and managers of plants with the advantages and fine points of the different types of filters, but inadequate attention has been given to instructing the operators. The results, so often recorded, of machines starting with capacities far in excess of requirements and a month later lacking capacity are due, time and again, to inefficient operation traceable to ignorance on the part of the operator. Superintendents should know the "tricks of the trade" in order to exercise intelligent control, but the operator should be the plant's expert on the particular material being handled and it should not be left to him to learn by graduating from the school of experience. That is too costly. To instruct him is cheaper and not difficult even with foreign unskilled labor.

To go into the detail necessary to bring out the underlying principles would make a single article too long, and it has been thought best to divide this subject into five papers with the separate headings; 1, Clarification; 2, Rate of Flow; 3, Washing and Drying; 4, Discharging; and 5, General Discussion and Auxiliaries. This is the first, on clarification, the others will appear in subsequent issues of this paper.

Clarification

Clarity of filtrate is in the vast majority of cases the primal object of the filter, but, as will be shown later, it is too often over-emphasized. When absolute clarity is not required, a different attack than will be here outlined is often possible.

The number of cases where capillary attraction and adsorptive action are real factors in clarification are relatively so few and far between that this general law can be defined: Clarity of filtration is due to superlative straining of the particles of suspension from the liquid in which they are suspended. This statement will doubtless call for criticism from some quarters, but it is held to be basic by reason of success obtained in handling a large number of problems completely ignoring capillary and adsorptive actions and concentrating solely on straining.

Open Woven Fabrics

The choice of straining or filter medium determines the nature of the straining or filtering. It is the popular belief that woven fabrics effect clarification by surface filtration; i.e., that the solids are caught on the surface of the fabric and build up to form a cake. Such a belief is rational when comparing a woven fabric to a granular bed filter medium. It is obvious that any particle penetrating the surface of a sand bed has opportunity to be caught in the interior of the bed before issuing from the false bottom as cloudy filtrate. Both theories are, however, subject to a liberal interpretation, for we have only to witness the number of times the filter cloth is clogged and not opened even though the surface be hand-cleaned with vigorous scrubbing and the cloth given reverse washes. Or, again, to watch the working of boiler feed-water filters wherein the initial flow is not clear and after running clear can run for a period only before the filter must be cleaned.

The answers are obvious. In the former, solids penetrate into the cloth and are firmly held in the meshes of the cloth—surely not true surface filtration. In the second case, clarification begins only when the retained solids form of themselves a filter medium on the top of the sand bed. The reason that the rate of flow is approximately constant in sand filters is that as the deposit on the bed builds up it has the effect of building up a resistance to the flow, increasing the filtering pressure. At some point this pressure builds up sufficiently to force the deposit through the surface of the sand bed and to work into the interior. Manifestly, if the filter is run long enough, the solids will issue through with the filtrate. In point of fact, therefore, the initial filtration through fabrics approximates filtration through-a-depth and with sand beds true clarification commences with surface filtration.

Surface Films

With the above in mind we have ground for the contention that too many industrial filters are equipped with too dense a filter cloth. Mechanical wear will often dictate the choice of a heavy cloth, but this should not be the signal to use a dense cloth. It cannot be expected that with the use of open cloths the initial clarity will be satisfactory, but it will be found that there is no hardship in refiltering the first runnings. Usually the filtrate brightens up readily and the amount to be returned can be added to the feed of the filter or else run through a separate filter which is used as a "polisher." Local conditions will govern the best means of handling this cloudy filtrate.

It is not practical to equip the filters with a more open cloth or a thinner fabric and not provide for the handling of cloudy filtrate. Absolute clarity can sometimes be obtained with such cloths by working with a low initial pressure, as for instance, gravity feed. There are cases where this is good practice, but as a general rule it is precarious, for it is required only that an insufficient deposit be made on the cloth when the pressure line is opened and the solids are pushed through into the filtrate. The basic idea is that the clarification shall be effected by virtue of the deposit of the solids on the filter cloth rather than that the cloth shall be the real medium. If this be carried out, it will be found that those particles which clog the dense cloth pass through into the filtrate so that the open cloth is maintained in a free filtering condition for recurring runs. This, of course, is obvious and need not be elaborated upon save to consider further the kind of cloth to use.

Use of Double Plies

It must be borne in mind that cotton is a cellulose product and with very few exceptions swells when immersed in liquids. Consequently, weaves that seem quite porous before wetting are quite dense afterward and similarly, loosely woven fabrics that will often seem flimsy when cut upon the table will prove quite substantial in practice. Many investigators have been impressed with the excellence of thin muslins, but have been deterred in their use by reason of their frailty. Such mediums are indeed very efficient, for they effect the nearest approach to instant surface filtration and by reason of the thin yarn from which they are woven do not clog up if their surface be cleaned—not enough thickness to hold solids.

The writer has seen installations where thin cloths were used, but in order to increase their strength two layers were used. This usually proves to be a poor expedient, for the conception that the inner cloth backs up any rent or tear of the outer cloth is not well founded. To obtain this result the two layers should be made integral one with the other by close lateral stitching or by spot pinning, etc. Then the possibility of a wrinkle in the outer cloth occurring at the point where the cloth is broken is decreased, but such a procedure has the same effect as if a heavy single cloth were used and there is no advantage worth the effort.

To prove the futility of double thicknesses of muslin one has but to inspect a filter so equipped that has been in operation a few days and note the accumulation of cake that occurs at the bottom of the leaves or plates. This increases with every run and is accounted for by the fact that the outer cloths are ripped or have "pin" holes, so that the under cloth must do the filtering at such points. More cake builds up than can clear through the hole when the filter is discharged, and this excess works down to the low point of the leaves.

Fabric Re-enforcement Gives Satisfaction

The idea of re-enforcing the muslin so as to strengthen it is good, but the under cloth must be of an excessively open weave such as "hose duck," burlap, cocoa matting or the like. Then any solids penetrating the muslin issue from the leaves as cloudy filtrate. It is amazing to what extent the muslin can be torn and still give good service under such conditions. The length of life of the muslin is then made positively practical even when using those machines that require the cloths to be sewn to the leaf. Diverse opinions have been rendered on this subject, but the writer is much impressed with the working of a battery of Sweetland filters having an aggregate filter area of over 7,000 sq.ft., where, after a thorough investigation was made of this point by several months' experimentation, muslin backed by burlap was used; the life of the muslin doubled, the output increased, and material economies were effected.

What is true about providing for cloudy filtrate when using cotton filter cloths is even more pertinent when using metallic cloths. These fabrics are designed as permanent mediums and their initial cost is justified only by their long life. Consequently, how much more fatal it is to allow these cloths to clog up. Users are the best judges of the delays and trials when caustic, acid and heat treatments are resorted to in order to regain their porosity. So much of this is needless if only provision be made to take care of cloudy filtrate and an open weave of uniform mesh be used. In a later article scale formation and its prevention on metal cloths will be dealt with and should not be confused with this subject of clarity.

Importance of the Form of Solids in the Cake

Much of the above is needless precaution for those handling materials with solids of a crystalline nature. There are niceties in their efficient handling, but there is none in respect to clarification save where some impurities are likewise present, the nature of which is not crystalline. In such cases the above is of positive importance.

A case occurred in a plant where calcium sulphate was thrown down from an acid liquor, but a considerable percentage of flocculent precipitates were present as well. The superintendent and chemist were advised of the advantage of using open cloths and tried them. They reported utter failure; the clarity never did become brilliant. One glance at their cakes as discharged from the filter told the whole story. As every filter manufacturer warns against the formation of tapering cakes due to inadequate agitation in the filter, they were informed on this point, but, in that they were not troubled with poor washing, had no difficulty discharging, and the leaves were not warped excessively, they were not equipped for thorough agitation in the machine. In consequence, with their open cloths the upper part of the leaves was subjected to the work of clarifying the lighter solids that were fine enough to penetrate the filter cloth and did not coat the surface with a substantial deposit. This instance serves to show the relation of agitation to clarity and also illustrates what small, insignificant factors can often be the deciding point between success and failure in this art of filtration.

Use of Filter-Aids

Decantation prior to filtration is often practiced and more opportunities are afforded these days for its use by reason of the excellent record of the continuous types of thickeners. The main advantage of decantation is in increasing the capacity of the filter with the possibility of using continuous machines in place of intermittent types. There are numerous cases where this procedure is eminently advantageous, but in the main it is confined to those materials that readily settle with a satisfactorily clear supernatant liquor. Where the

supernatant needs further clarification, the usual experience is that such a procedure is really "two bites at a cherry," and the clarification of the decanted liquor with its finely divided particles is a matter of nice control if anything approaching efficient operation is to be had. This clarification is made far simpler, however, if the solids are waste products such that a filter-aid may be added without chemically affecting the filtrate.

The use of filter-aids as agents assisting clarification is rightfully being recognized as efficacious, and they are being employed more and more. A filter-aid, whether the specific products on the market or a waste industrial material such as calcium sulphate, calcium carbonate, sawdust flour, pulverized bone-black, etc., must have three main properties. Its specific gravity must be such that when mixed in water or the liquid being filtered it will stay in suspension sufficiently to be easily handled in the filter; its filtering characteristics must be high and its chemical composition inert or harmless to the liquid. In this paper the discussion is confined to the use of filter-aids as clarification agents, and their use as aids in increasing the capacity, discharge, etc., reserved for later treatment.

Pre-Coating the Cloths

The fundamental use of a filter-aid as a clarification agent is in producing an auxiliary filter medium upon the filter cloth by means of "pre-coating." Pre-coating is the term used to define the initial filtration of a filter-aid before opening the main liquor line. This filtration is generally only for a minute or two, and it is sufficient when the effluent issuing from the filter is brilliant. Too often the impression seems to be that this coating must be of some sensible thickness, one-eighth or one-sixteenth of an inch, where, in fact, a film is quite sufficient. On raw sugar liquors it is practical to pre-coat the cloths, using 1 lb. of "filter-cel" per 100 sq.ft. of filter surface, and on examination of a filter leaf after coating it will seem to be without any deposit, but the clarity of the filtrate will be found to be brilliant when filtering the sugar liquor and a white surface will be noted on the inner face of the cake when discharged. This is possibly the minimum amount to use and safer results are obtained by doubling this amount, but even this will give a coating difficult to measure and no liquors have been encountered, to date, that will not give brilliant filtrate through it. Obviously, more than this is an extravagant use of the material and unnecessarily increases the initial resistance of the medium.

Methods of Applying Filter-Aids

The vehicle to use for this pre-coating is a matter for local decision, but there are three methods in practical use giving eminent satisfaction. First, to make up a slurry of the filter-aid and water (or when handling varnishes, etc., some solvent), and to filter it in the usual manner, shutting off when the filtrate is brilliant. In most machines the amount of unfiltered slurry demands its withdrawal from the filter before admitting the sludge. Best practice, therefore, is to locate the slurry mixing tank below the filter so that the excess unfiltered in the machine may be drained back, using the minimum of air pressure to hold the coating on the cloths.

To obviate this draining back some plants use the second method, where clarified effluent is used instead of water or the solvent and sufficient filter-aid is added to insure a pre-coat when the following operation is carried out. The pre-coating liquor is admitted to the filter until full, when the regular liquor is fed to the machine. Experience shows that the first deposit on the cloths is the filter-aid and that there is no trouble in getting clarity nor in dealing with excess unfiltered liquors. The layout for this method is usually to locate the pre-coating tank above the filter so that no pump is necessary to feed the pre-coating slurry to the filter, gravity feed with large pipe lines being sufficient.

The last method is that so extensively used in the sugar refineries of the United States and Canada. Here the solids of suspension in the liquors to be clarified are present in relatively low percentages and it is found quite practical simply to add sufficient filter-aid to the unfiltered material so that the volume of the filter-aid far exceeds that of the original solids. This liquor may then be fed as in the second method. The coating will be found to be such a close approximation to straight filter-aid that the practical results are the same.

Where positive clarity of filtrate is essential, as in the manufacture of artificial silk, this scheme of an auxiliary medium is well nigh indispensable. Local conditions may exact some research in order to find that filter-aid best suited to the requirements, for while "filter-cel" is almost a universal material, it is not best when handling heavy caustics or some food products, to which the "filter-cel" imparts a detrimental taste. In any case, however, to persevere and find the right material will be found well worth the effort.

(Part II, dealing with the Rate of Flow, will be published in a subsequent issue.)

Growth of Manufacturing Industries in New South Wales

Figures released in January by the statistician of the government of New South Wales show that the industrial growth of that state has been rather limited, as the number of manufacturing establishments increased only from 5,269 to 5,450, involving an increase during this period of only 9,870 in the number of employees, or 1.7 per cent per annum, making a total of 126,481 of such employees on March 31, 1919. The male adult workers, whose salaries averaged $636.48 in 1914-15, averaged $764.89 in 1918-19, which have been further increased by the all-around advance of about $4.12 per week, following the Board of Trade's decision that the basic wage should be $18.84 per week. During the same period the total output of factories in the state increased in value from $331,511,193 in 1914-15 to $509,224,467 in 1918-19, but a large portion of the increase indicated is due to increased values rather than to output.

Chicle Gum in British Guiana

Announcement has been made in a report submitted by Consul McCunn of the discovery of chicle-producing trees in British Guiana. Prospecting expeditions sent into the interior have recently returned to Georgetown with full 600 lb. of chicle, and preparations are now being made by the discoverer, who holds a concessional right over 6,200 square miles of territory, to send out four prospecting parties in order to continue investigations and ascertain the capacity of the tract. Territory thus far examined is reported to be capable of yielding 200,000 lb. of gum annually.

Calcium Molybdate as an Addition Agent in Steel Making

By Alan Kissock

IN THE production of alloy steel, molybdenum, like most similar metals, is commonly added to a steel bath in the form of a ferro-alloy, usually less than a half an hour before the furnace is tapped.

In the open-hearth furnace practice varies, from melting the ferro in a small electric furnace and making a hot metal addition, to crushing to about one-quarter mesh and adding it cold, or, as is perhaps most common at present, the alloy is thrown into the furnace, container and all, just as it comes from the manufacturer. In the electric furnace, with its more concentrated heat, the manner of introduction is of lesser importance.

Formerly a ferro containing from 75 to 80 per cent molybdenum was generally specified. Because of the difficulty of securing an ore suitable for manufacturing such a high-grade alloy, and because of the high melting point of the metal, with attendant difficulties of production, the cost of this alloy was necessarily high. In the continued attempt to decrease production cost, and since there can be no real objection on the part of the steel manufacturers, more recent practice has been to produce a ferro containing approximately 50 per cent molybdenum. This grade of ferro, besides being less costly to produce, is perhaps the principal factor in the success of its direct addition to steel. Its lower melting point is responsible for less segregation and eliminates the necessity of pre-melting or fine crushing.

Merit and Cost of Molybdenum

In the attempt to create or stimulate the use of anything new, the first requirement is to establish its merit and secondly to decrease its cost. The first requisite—the value of molybdenum as an alloy for certain steels—is continually becoming better known. Principally from lack of demand, the war-time price of ferromolybdenum has fallen considerably, but if the metal is to find extensive use it is necessary that a reasonable and more constant cost be established.

In deposits of commercial extent, molybdenum seldom occurs in percentages sufficient to permit, even by the most efficient known means of ore concentration, a recovery of greater than 10 lb. of metal per ton of crude ore mined. Often considerably less may be extracted. A great many costs, therefore, must be charged against these few pounds of metal recovered, from the mining, through the often-difficult concentration, to the final transportation.

To these must be added the cost of electric smelting with its heavy losses, even in the best of practice, the difficulties of coming within the customarily rigid specifications of the consumer, and the uncertainty of selling the product when finished. It is easily seen, therefore, that if a fair and reasonable return is to be made to the producer, ferromolybdenum cannot become cheap enough to compete largely with some of the more common steel-alloying elements. Assume that every possible cost of mining and treatment has been brought to its lowest point. Then if any further decrease in cost is to be obtained, it becomes possible only through some improvement in the metallurgical treatment or through the elimination of some step in the preparation of a suitable product for the steel manufacturer.

With these facts in mind, it occurred that it might be possible successfully to introduce molybdenum into steel by the use of a salt of the metal rather than by the use of ferromolybdenum. Could this be efficiently accomplished, then the electric-furnace reduction of ores and products would be eliminated and in its place a much lower-cost chemical treatment could be substituted.*

Chemical Compounds as Addition Agents

The idea of introducing an alloying metal into steel by means of some salt or compound thereof is not particularly new. It has been tried, both in the furnace and in the ladle, with certain of the metals, and with more or less success. Several difficulties, however, are encountered in considering the more common salts or compounds of molybdenum.

The ordinary 60 per cent molybdenite concentrate, or even the higher grade, is unfit for direct addition for several reasons. All such concentrates contain a certain proportion of silica and in basic furnace practice it is desirable to avoid, as far as possible, any introduction of silica into the bath. Upon addition of molybdenite to steel at least a portion of the ore would be converted into the trioxide and as such would readily volatilize and be lost. The most serious objection, however, is the 25 to 30 per cent sulphur content of high-grade concentrates. In a test made at the plant of the Southern California Iron & Steel Co. in Los Angeles, an attempt was made, by the addition of high-grade molybdenite, to introduce 0.4 per cent molybdenum into steel. It was found that although a considerable proportion of the molybdenum entered the steel, sulphur, with its great affinity for iron, was also introduced to the extent of 0.25 per cent. By long treatment in the furnace, with manganese and lime additions, this sulphur content might have been lowered, but with the furnace-man's constant effort to keep the sulphur low in his product, a molybdenite would hardly be looked upon with favor.

Roasted molybdenite concentrate or trioxide of molybdenum would serve as a direct addition agent, were it not for the ease with which this compound is volatilized. At 1,200 deg. F. the vapor pressure of molybdic oxide is quite high, so that recoveries from an addition at steel-furnace temperatures would be unprofitably low. Such roasted concentrates would also carry the silica gangue of the unroasted material, and though it is possible to manufacture a more pure trioxide, the cost of such is prohibitive.

Since molybdenum unites in varying proportions with oxygen, it is possible that one or more oxides might be found which would not be volatile at furnace temperatures. The difficulty, however, of efficiently producing such oxides makes such compounds of doubtful value for consideration as addition agents.

Sodium molybdate might serve as another possible agent but for the higher cost of producing it of a sufficiently high molybdenum content.

In the case of some molybdenum ores, a step between concentration and the manufacture of ferro involves either a furnace or a chemical treatment for the removal of possible impurities and the production of an alkaline salt of molybdenum, preferably calcium molybdate. Although in the production of ferro from molybdenite it is not always necessary to precede electric furnac-

*Compare, for instance, J. P. Bonardi, "Notes on the Metallurgy of Wulfenite," Chem. & Met. Eng., vol. 21, p. 364, Sept. 15, 1919.

ing by a roast or wet treatment, such a process can be readily applied and a calcium molybdate of high grade very easily produced.

Theoretically, calcium molybdate should serve as an excellent addition agent to steel. It can be easily and comparatively inexpensively made of a high grade, containing practically nothing but the oxides of molybdenum and calcium. The salt is easily reduced and the lime apparently prevents loss by volatilization of the molybdenum trioxide. Upon reduction of the molybdenum, by the carbon or silicon in the steel, the lime would simply serve as a small added source of material for the ordinary basic slag.

Early in 1918, in New York City, several small steel heats were made. An experimental electric furnace was employed and molybdenum was successfully introduced by the use of calcium molybdate with a recovery of 95 per cent.

Encouraged by these tests and with the kind co-operation of P. E. McKinney, metallurgist at the U. S. Naval Gun factory, a commercial test was made at the Navy Yard in Washington, in September, 1918. The calcium molybdate was made from the wulfenite ores of the Mammoth Development Co. of Los Angeles, and furnished gratis by that company for the test. Using a Heroult furnace, six tons of scrap was melted and at the proper time sufficient calcium molybdate added to introduce about 1 per cent molybdenum into the steel. The molybdenum content of the product, as shown by final analysis, confirmed commercially the previous experimental results. At a later date, C. E. Margerum, metallurgist of the U. S. Naval Ordnance plant at Charleston, W. Va., repeated the success secured at the Navy Yard in Washington. A third electric-furnace test was made at the plant of the Carbon Steel Co. in Pittsburgh, Pa. A 6-ton Heroult furnace was employed, and a repetition of the success of the two previous heats gave ample assurance that calcium molybdate was a satisfactory addition agent for use in the electric furnace.

Molybdate in the Open Hearth

Having succeeded in these attempts, it was conceded that because of the strong reducing action of the electric furnace, the results obtained were to be expected. That the same success could be secured in the strongly oxidizing atmosphere and action of the open-hearth furnace was, however, open to argument, and considerable skepticism had to be overcome.

Experimentation has shown molybdenum to have less affinity for oxygen than either iron or carbon. Industrially, this is again proved by the fact that once in the steel bath neither "oreing down" nor "boiling" appears to lower the molybdenum content.

Provided the molybdate could come in direct contact with the molten metal, it was thought that the salt might be reduced either by the metallic iron itself or by one of its reducing constituents. By the courteous aid of the officials of the Carbon Steel Co., 50 tons of pig iron and scrap was charged into one of the basic open hearths at their plant in Pittsburgh during November, 1918. At the proper time sufficient calcium molybdate was added to introduce the desired percentage of metal. Analysis of the ingots produced showed a high recovery of the molybdenum added, and the success so attained amply rewarded the effort expended.

Early in May, 1919, with the kind interest and co-operation of the staff of the United Alloy Steel Corporation, a second open-hearth test was arranged. Two 100-ton heats and a third but smaller basic furnace heat were made and the desired amount of calcium molybdate added in each case. The practically complete recoveries of molybdenum secured proved beyond question that molybdenum in this form may be successfully, and very efficiently, introduced into steel made in the open-hearth. In all tests, rolling mill recoveries correspond with those usually obtained with the customary ferro addition.

In order that the molybdate may come in direct contact with the molten iron, it is necessary that the addition be made in the early stages of the heat. In one of the tests the molybdenum was in the open-hearth furnace over a 14-hr. period and under very severe oxidizing conditions. The fact that the molybdenum content remained practically constant is proof of another very important consideration in connection with the metal. It is conclusive evidence that molybdenum, like nickel, and unlike vanadium, "stays" with steel. In the use of molybdenum, therefore, the "crops" and scrap ordinarily encountered in all alloy steel manufacture can be remelted with but little loss, thereby reducing the amount of alloying metal required. Because of the economy that may be effected, the importance of this fact must be appreciated when considering molybdenum as an alloying metal to replace certain of the metals now being used, and for purposes in which it may serve equally well.

Method of Operation

The introduction of molybdenum into steel by means of calcium molybdate involves no complications whatever, it being only necessary to bear the following in mind:

With the strongly reducing action and concentrated heat of the electric furnace, the time of addition is of less importance. Best results have been secured by introducing the molybdate immediately after skimming of the first, or phosphorus slag, the final or white slag indicating, of course, that reduction has been complete.

In open-hearth practice, the molybdate must be added in the early stages of the heat, not with the charge because of possible loss in the furnace bottom, but preferably a little before the melt becomes "level." In other words, in any type of furnace it is only necessary to remember that the molybdate must come in *direct contact with the molten iron*, and therefore in the basic open-hearth it must be added just before the lime begins to come up. A layer of slag would completely prevent contact with the metal. Shipped in sheet iron drums of convenient size, the molybdate is added, containers and all.*

Advantages

From the standpoint of the miner the production of calcium molybdate is particularly advantageous. In almost every occurrence, molybdenite is associated with considerable percentages of both iron and copper sulphides. In order to produce a marketable concentrate, all of the copper and a considerable portion of the iron

*All rights to the process as outlined, both in the United States and foreign countries, are covered in U. S. Pat. 1,299,115 and are owned by the Steel Alloys Co., Investment Building, Los Angeles, Cal. It has been arranged that license to use the process will be furnished gratis by the Steel Alloys Co. to any steel company that may purchase calcium molybdate from such molybdenum producers or sellers as may be specified upon the license. Since it is expected, however, that the arrangement mentioned will be made with all potential consumers, profits to be distributed to the steel manufacturer, either in payment of royalty or limiting of purchasing power, will be elected.

must be removed. This may be accomplished by selective flotation, but this cleaning process not only adds to the operating costs but invariably means a lower extraction. In other words, any refining operation, whether it be in concentration or in the electric furnace production of ferro, is necessarily a costly one. Neither copper nor iron interferes in the production of calcium molybdate, so that the need of either of these refining operations is entirely eliminated. It therefore becomes unnecessary for the miner to make a high-grade concentrate or to separate therefrom any of the copper or iron sulphides that might be contained. The millman will readily appreciate the saving that may thus be effected.

The production of calcium molybdate offers a further advantage in that the equipment for its manufacture does not involve great cost nor is especial skill required in the operation. The method is comparable to the cyanide process in that large tonnages may be readily treated and in many cases such may be carried out right at the mine. The electric-furnace production of ferro not only requires very large expenditures for tonnage treatment, but also necessitates particular experience and skill. Only in rare cases is the mining company in position to carry out such an operation, and it thus becomes dependent on some metallurgical concern to put its product into marketable form.

Calcium molybdate is readily made, and with high recovery, from all molybdenum ores by simple chemical treatment. The salt as usually furnished carries approximately 40 per cent metallic molybdenum and contains no impurities detrimental to good steel manufacture. It has been proved beyond question that molybdenum, in this form, is a very efficient addition agent for the introduction of the metal into steel.

The particular advantage of the process is that a carbon-free molybdenum addition agent may be afforded to the steel manufacturer at a price which will assuredly permit the competition of the metal with those at present in more general use. It is not within the scope of this article to attempt to point out the use or benefits of molybdenum in steel. The value of alloy steel in general is constantly becoming better appreciated. In the writer's opinion, molybdenum is the only metal commercially available in this country which is capable of developing in steels properties equivalent to those produced by metals which must now be imported. A possible strategic value exists in the ample and constant domestic supply of molybdenum that is now assured. From the results of the work that is being done by concerns, as well as individuals of prominence, it is certain that molybdenum will shortly fill an important place in the alloy steel industry.

Los Angeles, Cal.

Radium Scarcity

Owing to the scarcity of radium—which is now priced at $78,000 a gram—and the failure to discover new sources of supply, it is feared the shortage will become exceedingly acute. In the meantime, it is reported that radium for use in medical research is being prepared by a special method. A weak solution is made which gives off radium emanations; these, which are detected only by delicate instruments, are collected in tiny sealed glass vials and the vials are sent to medical men. It is stated that the efficacy of such bottled emanations lasts one week.

World Production of Coal in 1919

The world's production of coal in 1919 seems to have dropped back to the level of 1910. Preliminary estimates, necessarily rough, place the total output of all kinds of coal in 1919 at 1,170,000,000 metric tons, or 1,290,000,000 net tons. This is 162,000,000 metric tons less than the production in 1918, the last year of the World War, and about 171,000,000 tons less than that of 1913, the year before the war began.

This estimate is based by the Geological Survey upon reports to the Supreme Economic Council from countries which contribute about 85 per cent of the world's output. Obviously, returns from the other countries may materially alter this figure; if anything, they will probably reduce it still further.

The following table shows the estimated production of the world for each year from 1910 to 1919. Because of disturbances and interruptions in the compilations of Government statistics, particularly in central and eastern Europe, the figures since 1913 are not to be regarded as final. The metric ton of 2,205 lb. is used because it is the prevailing unit in non-English speaking countries. Americans will remember it most easily as being roughly equivalent to the gross ton and the English ton.

WORLD'S PRODUCTION OF COAL 1910-1919
(Metric Tons of 2,205 lb.)

Year	Production, in Part Estimated	Per Cent Produced by U. S.	Year	Production, in Part Estimated	Per Cent Produced by U. S.
1910	1,160,000,000	39.2	1915	1,190,000,000	40.5
1911	1,189,000,000	37.9	1916	1,270,000,000	42.1
1912	1,249,000,000	38.8	1917	1,336,000,000	44.2
1913	1,341,000,000	38.5	1918	1,332,000,000	46.2
1914	1,208,000,000	38.5	1919	1,170,000,000	42.1

Comparative production in five of the belligerent countries before and after the war is shown in the following table:

PRODUCTION OF COAL IN CERTAIN COUNTRIES, 1913 AND 1919
(In Millions of Metric Tons)

	1913	1919
United Kingdom	292	237
France (present boundaries)*a*	44	22
Belgium	23	18
Germany (present boundaries)*b*:		
Bituminous	173	109
Lignite	87	94
United States	517	494

(*a*) Includes Alsace-Lorraine. (*b*) Excludes Alsace-Lorraine and the Saar.

It is pointed out by the Supreme Economic Council that from 1913 to 1919 the output of bituminous coal in the four European countries shown in the table has fallen from 532,000,000 to 386,000,000, the decrease being about 20 per cent in the United Kingdom and Belgium, and nearly 40 per cent in Germany. In the Saar Valley, whose output appears to have fallen from 12,000,000 tons in 1913 to about 8,000,000 in 1919, the percentage of decrease was over 30. The reduction in the French output is mainly due to the destruction of the mines in the Nord and Pas de Calais.

The output of lignite in Germany in 1919, though less than in 1918, was still greater than before the war, being 94,000,000 tons, as compared with 87,000,000 in 1913.

In the break-up of Austria-Hungary the bulk of that country's coal and lignite, the production of which amounted before the war to about 55,000,000 tons, was inherited by the Republic of Czechoslovakia. The 1919 production of Czechoslovakia was about one-third less than the same territory produced in 1913.

The Fertilizer Situation

A Statement of the Present Tendencies of the Fertilizer Industry—Fewer Brands—Thermal Phosphoric Acid Processes—Theory of Fertilizer Use—Solution Method of Applying Concentrated Fertilizer Salts

By MILTON WHITNEY

TO ANYONE who has given careful thought to the fertilizer situation for the past few years, especially since 1913, there is evidence of a profound change taking place not only in the methods of sale but in the fundamental methods of manufacture. It has been long recognized that the old trade or brand names have outlived their usefulness with the organization of capital and the merging of small interests into great enterprises. With the advent of the European war and the consequent shortage of material and uncertainties as to supplies, it was realized that many of these brands could not be maintained, and they were merged into uniform grades without material effect upon the volume of the trade in commercial fertilizers. The advantages they were supposed to give competitors handling comparatively small amounts of material were found to be a liability of the larger concern because of the increased cost of manufacture, printing and distribution. From one point of view they may have served a useful purpose, but that day is now past, and they must be discarded. From another point of view they were detrimental in that they retarded to some extent the passage of the fertilizer trade into the real chemical industry that it is destined to become.

Conservation of Phosphate

Even before the war emphasized the limitations of rail transportation and the necessity for greater conservation than in the past, it was recognized that the enormous losses entailed in the mining and marketing of the large annual output of Florida and Tennessee phosphates made it of the utmost importance that some adequate scheme be devised to conserve our phosphate deposits. Practically all of the rock mined at present is converted into superphosphate by treatment with sulphuric acid. The acid phosphate manufacturers demand a rock notably free from iron, alumina and calcium carbonate. As a consequence it has been estimated that for every ton of rock that is converted into the superphosphate by treatment with sulphuric acid two tons are discarded as unsuitable for such treatment. The Bureau of Soils is at present conducting investigations which it is hoped will lead to the development of a method by which phosphoric acid may be profitably obtained from this discarded material. It is worthless so far as sulphuric acid treatment is concerned. Its only salvation lies in another method. If the Bureau of Soils plan succeeds, it will mean the conservation of by far the greater part of our phosphate deposits.

The fusion of a mixture of phosphate rock, sand and coke in an electric furnace permits the volatilization and subsequent collection by the Cottrell precipitator of phosphoric acid of satisfactory purity and concentration. If water power could be obtained around $6 per hp.-yr., this method would be adapted to commercial production, but at the present price, $20 to $25, the cost of production of phosphoric acid by the electric furnace is about three-quarters of a cent higher than by sulphuric acid treatment. Moreover, it is not likely that water power will ever be available in large quantity at a price sufficiently low to warrant its use in the production of phosphoric acid, which must be sold on the ton basis, when there is such a large and rapidly increasing demand for power by producers of the more expensive chemicals sold on the pound basis. Recent work in which oil fuel is used as the heating agent, instead of the electric furnace, gives promise of a commercial method for preparing phosphoric acid.

Advantages and Disadvantages of Phosphoric Acid

There are certain advantages and certain disadvantages in the use of phosphoric acid. One of the disadvantages is the difficulty attending the transportation of a corrosive liquid. However, this can be readily overcome by converting the acid into one of its soluble solid salts, as will be shown later. Some of the advantages are that it can be produced at the mine from mine-run material, since the presence of impurities which offer objections in the case of sulphuric acid treatment are actually necessary for successful furnace treatment. If the rock is high grade, sand must be added to displace the phosphoric acid. The presence of relatively large percentages of alumina, instead of being a drawback, greatly facilitates the smelting of the phosphate charge. The mine-run material, therefore, is generally more suitable for fusion work than high-grade rock.

It seems best to convert the phosphoric acid thus produced into a solid salt by neutralizing it with ammonia or potash. The substitution of these bases for lime saves a considerable part of the freight and provides a soluble product which does not revert to an insoluble compound, as is the case with acid calcium phosphate. While the saving of the rock which is now thrown on the dump was the primary cause of the investigation which is being conducted by the Bureau of Soils, it now develops that the fusion process will have other advantages in that several of the products from the nitrogen-fixation plants can be freely mixed with ammonium or potassium phosphate, which cannot be mixed with the acid calcium phosphate without reversion of the latter and decomposition of the fixed-nitrogen product.

The fertilizer industry of the past has been largely a scavenger industry, using materials that were formerly waste products, some of which were even detrimental to health. One of the first of these products to go into commercial fertilizers was cotton seed and cottonseed meal, then the fish scrap, an offal from the fish houses, then animal tankage and refuse from the slaughter houses.

Unlike European practice, where fertilizer constituents are generally applied singly from time to time, the American practice has been to use mixed fertilizers and make only one application. A theoretically ideal mixed fertilizer must contain three representatives of nature's nitrogen cycle, phosphoric acid and potash. Nitrate nitrogen is immediately available for plant use and nourishes it in the very earliest stages of growth, while the nitrogen of ammonium salts becomes available only after it has been oxidized to the nitrate condition by processes that take place slowly in the soil; hence a supply of nitrogen is furnished the plant at a later period of its growth. The third representative of the nitrogen cycle above referred to is the so-called organic ammoniate or protein body. These bodies must undergo still more complex changes, requiring a correspondingly longer period of time. The soil must first convert the protein into an ammonium compound, then oxidize the ammonium salt to nitrite and finally to nitrate before the nitrogen can be taken up by the plant. In the time required for this transformation, the plant has probably reached the last stages of its development.

Organic Ammoniates for Feeds

Some years ago it was found that some of the organic ammoniates used for fertilizers could be used as concentrated feeds for animals. As a result of the European war and the efforts made to increase animal production, these organic ammoniates have gone more and more into feeding purposes. Up to the beginning of the war, the price of the organic ammoniates was controlled in a way by the world price of nitrogen in nitrate of soda.

In October, 1919, the department called a conference of producers of tankage, dried blood, fish scrap and cottonseed meal in order to ascertain why the price of nitrogen in these forms had not followed the drop in the price of nitrogen in nitrate of soda and ammonium sulphate. It was very clearly shown at that conference that changes of great magnitude had been going on and that the bulk of these materials is now being used for feeding purposes, and that their price per ton was regulated not by the price of nitrate of soda but by the price of other feeding stuffs. Today the competition between feeders and fertilizer manufacturers for these organic ammoniates is very great and is the subject of frequent comment in the trade journals. The cost of nitrogen is fully twice as great in the organic ammoniates as in mineral compounds. Judged by fertilizer standards, cottonseed meal at $80 a ton has become a luxury, while from the feeding standpoint, comparing its protein content with other feeds, its price is low as a feeding material. It is unlikely, therefore, that the price will decline materially or that the farmers will stand for the fertilizer manufacturers bidding for material against the feeders.

Increasing Scarcity of Organic Ammoniates a Source of Concern

The increasing scarcity, not to speak of the high prices, of organic ammoniates for fertilizers has been a source of real concern to the fertilizer manufacturer, for not only are these ammoniates in great demand as a source of nitrogen to make up their ideal of mixed fertilizer, but they are also depended upon to give the finished goods the proper mechanical texture. In the South generally cottonseed meal has been used as a conditioner; in the North tankage, fish scrap and dried blood. Mixtures consisting of ammonium salts, potassium salts and acid phosphate are likely to cake and harden in the bags and hence are not as easy of application as when mixed with organic matter. What to use as a conditioner is beginning to be a real problem. Dried ground peat is one of the natural materials that suggests itself as a substitute, but it is just as expensive to prepare peat as it is to dry and grind tankage. The value of peat is mainly as a conditioner, while tankage, cottonseed meal and fish scrap have an intrinsic value in their available nitrogen content.

Dependence of Nitrogen Supply on Other Industries

It seems rather illogical to depend so largely for our nitrogen supply upon the amount of cotton grown, the number of animals slaughtered or the quantity of fish caught, when it is well known that these have been limiting factors in the manufacture of fertilizers and have been always wholly inadequate to the needs of the country in order to fertilize properly such staple crops as wheat and corn. The use of fertilizer is advancing westward year by year and the demand for it will certainly increase much more rapidly than waste products can be made available, even if these were not being converted into feeds, but with this conversion the situation is serious in the extreme. Some realized before the war that we should have to come to fixed-nitrogen products. Few realize now that these fixed-nitrogen products are essential to maintain and to increase our crop yields by the extensive use of fertilizers. The developments of the war in the production of munitions have shown the lines along which this fixed-nitrogen problem is likely to be worked out and the commercial practicability.

Fixed-Nitrogen Products as Fertilizers

There are two main products that have heretofore been made on a large scale for munitions which can be utilized for fertilizer purposes. Calcium cyanamide is probably the cheapest form of fixed nitrogen, but this product is not entirely satisfactory. It can be used only in small quantity in our mixed fertilizers because it reverts the acid phosphate, and has in addition certain disadvantages in direct application to the soil. While some of the disadvantages of this material may be overcome, it has not been received with universal favor in Europe, where it has been longest used. The American farmers would have to change their methods of applying fertilizers in order to use a material which cannot be safely mixed with other fertilizer ingredient.

The other product of the nitrogen-fixation plants is ammonia. Ammonia may be oxidized to nitric acid and applied to the soil in the form of a salt of this acid, or the ammonia may be neutralized with sulphuric or phosphoric or nitric acid and used in the form of ammonium sulphate, phosphate or nitrate. Ammonium sulphate is well known in American agriculture at the present time, it being a byproduct of the coke industry. Ammonium nitrate is a new product to American agriculture. It is a much more concentrated form of nitrogen than ammonium sulphate, and it, therefore, carries a smaller cost per unit of nitrogen for transportation. On the other hand, it is highly deliquescent and has the further disadvantage that it can be mixed in only small amounts with other fertilizer ingredients, as in larger amounts it reverts the phosphoric acid and there

is a loss of nitrogen. Ammonium phosphate is equally new to American agriculture and is a highly concentrated fertilizer material.

Use of Fixed-Nitrogen Products

This leads to a consideration of how to use these fixed-nitrogen products. It has been shown that if phosphoric acid is abstracted from the rock there is economy in freight and in conservation of our phosphate deposits. Ammonium phosphate prepared by mixing ammonia from the nitrogen-fixation plant with phosphoric acid produced at the mine may be mixed in any proportion with ammonium nitrate, and if to this combination potassium phosphate be added, a mixture is obtained which is apparently not deliquescent, which does not undergo chemical change and which is the most concentrated form that it is possible to make a fertilizer and in which every constituent pays its own transportation charges. It contains two forms of nitrogen, but the third form—organic nitrogen—is missing.

When these stable salts of dipotassium phosphate, monoammonium phosphate and ammonium nitrate are mixed in the proportion to give a fertilizer of the formula 2-8-2—2 per cent nitrogen, 8 per cent phosphoric acid (P_2O_5) and 2 per cent potash (K_2O)—the mixture is so concentrated that it would require only only 326.4 lb. of the combined salts to make a ton, making it necessary to use 1,674.6 lb. of filler if it is to be diluted to the usual strength of the fertilizer of that composition. It could, however, be used in its concentrated form. A mixed fertilizer having the formula 4-8-4 would require 75.91 per cent filler to give the dilution in an ordinary fertilizer of that composition. A mixed fertilizer of 4-8-10 would require 69.6 per cent filler and one of 10-8-4 would require 58.76 per cent filler to give the usual dilution.

Method of Application of Concentrated Chemical Fertilizer

These mixtures are all completely soluble in water. They could be applied to the soil in the concentrated form of crystals, just as nitrate of soda is applied or as acid phosphate is applied. If it is desirable to maintain the degree of dilution in ordinary fertilizers, they could be locally mixed with peat or any similar substances in the proportion above given. The one filler that costs nothing and is readily accessible to all is water. In other words, the fertilizers could be dissolved in water and spread on the surface or applied in the drill. This would of course involve some change in farm implements, but not a very serious one. It seems to the writer that it would be of great advantage to the intelligent farmer to be able to obtain the separate ingredients, and by dissolving them separately in water and then mixing the resulting concentrated aqueous solutions in proper proportions to obtain a complete fertilizer of any desired composition. There would be the further advantage of uniform distribution and immediate and thorough incorporation in the soil.

Objection may be made that the solutions of the fertilizer salts would be too concentrated for ordinary application. An alternative method would be the mixing of such a solution with a definite amount of soil or sand and distributing this mixture in the same way as fertilizers are ordinarily distributed at present. This would not involve the use of any new machinery or any change in the present methods of agriculture. As an illustration, a complete fertilizer of the composition 4-8-4 would be made up as follows: Weigh out 148 lb. of K_2HPO_4, 161 lb. of $NH_4H_2PO_4$ and 173 lb. NH_4NO_3 and dissolve them in 182 gal. of water.

The advantages and disadvantages of such fertilizers may be summed up as follows: It must be admitted that the absence of the organic ammoniates is a distinct disadvantage in that it takes away a material that supplies the plant with nitrogen during the last stages of its development. On the other hand, the saving of freight and drayage, the more thorough mixing with the soil at the time of application and the ease with which subsequent applications can be made to the growing crop, either of the entire formula or any part of it as desired, are all advantages.

Preparation of Dipotassium Phosphate

Mention has been made of the proposed use of dipotassium phosphate in these mixtures as the most concentrated salt of potash in mixed fertilizers. This raises the practical question of the commercial preparation of such a salt from materials available. It has been established by numerous experiments that if potash shales are mixed with phosphate rock and coke, the shale taking the place of sand that is ordinarily added, the fusion takes place equally well and that part of the potash is volatilized and caught in the Cottrell precipitator as a monopotassium phosphate. The experiments have not proceeded far enough to indicate whether the evacuation of the phosphoric acid is as complete with the shale as with the sand, but there seems to be a possibility of collecting the two materials in one and the same operation. The monopotassium phosphate should be converted into the dipotassium phosphate to increase the percentage of potash in the salt and also on account of the greater stability of the latter salt. The conversion could be readily effected by mixing the monopotassium phosphate with potassium carbonate, which is now produced in considerable quantities from some of the deposits in this country. The most common salt of potassium used in this country for fertilizer purposes is the chloride. Potassium chloride mixed in the proper proportion with phosphoric acid and the mixture heated would yield dipotassium phosphate, and hydrochloric acid would be evolved. Hydrochloric acid is of considerable commercial value, and its sale would probably pay for the energy expended in converting.

Summary

This review of the fertilizer situation is not intended as exhaustive. Space does not permit the tabulation of figures, and perhaps they are not necessary. The statements made and the illustrations used will have served their purpose if attention is drawn to the fact that the fertilizer industry of today and of the future is bound to be a chemical industry based upon chemical investigations and control, instead of the scavenger and rather vague industry of the past, and if we come to realize that the time has arrived when we must meet the situation in a somewhat different point of view from that which has prevailed. The fertilizer industry has passed through the trying period of the war, and it has emerged upon a stronger and much more substantial basis than it had before the war. Changes must occur. It was foreseen that they must occur. The result has been to bring them more prominently before us and to establish the industry on a still more substantial basis.

Instruction in Iron and Steel at M. I. T.

By Carle R. Hayward

THE course which is described here is that required of students taking the metallurgical option in the department of mining and metallurgy at the Massachusetts Institute of Technology. Other students with adequate preparation may take the course if they desire. In addition to the field covered in this course the students receive instruction in iron and steel analysis in the chemical department, testing materials in the mechanical department and a thorough course in metallography and heat treatment which give them a knowledge of the chemical, mechanical and physical properties of iron and steel.

In a recent reorganization of the course some new features were introduced which have increased the interest of the students and at the same time given them a more thorough grounding in the subject.

Changes Made to Meet Criticism

The first of these changes was to meet a criticism, often heard, that the tendency in college work is to give the students "spoon feeding" in lecture courses instead of throwing them on their own resources. The lectures were accordingly cut to twenty hours, with an additional twenty hours allowed for preparation. It is obvious that only basic principles can be pointed out in this time and references given to the literature for details.

The time set free from class-room work is used in the library. The students are directed in their reading by assigning references to the files of technical journals or standard treatises on the different phases of iron and steel operations. In order to assure a thorough search of the literature five subjects are assigned on which concise summaries are to be prepared. The subjects of these papers may vary in different terms. Those used by the last class were as follows: 1. Blast-furnace construction. 2. The chemistry of the blast furnace. 3. The chemistry of the open-hearth processes. 4. Piping and segregation in ingots and castings. 5. The production of malleable castings and case-hardened steel.

It has been found that the students have taken a great interest in this part of the work and the net results have been very satisfactory. The library is used as never before and a familiarity cultivated with standard works and periodicals.

Neighboring Plants Visited

Another feature of the course which has proved both profitable and beneficial is the visiting of such plants as are available about Boston. These visits are part of the required work and each student writes a report of the trip. After the reports are completed the class meets to discuss the various operations and clear up any obscure points. The management of the different plants, realizing that these visits are part of the required work of the course, have heartily co-operated in this plan, which has contributed much to its success.

Although there are no iron blast furnaces in the vicinity of Boston, it is possible to study open-hearth practice and steel rolling at the American Steel & Wire Co.'s plant at Worcester, steel foundry work with open-hearth and electric furnaces, together with forging and heat treatment, at the Watertown Arsenal and other operations such as Tropenas converter practice, cast iron practice in cupolas and air furnaces, drop forging, etc., in various plants.

During the summer some of the men get positions in well-known steel plants, where they get practical experience which is valuable either before or after taking the course.

It is too early to judge the final results of this plan of teaching, but the indications are that the variety of instruction gets and holds the interest of the students and sends them out better equipped to meet actual plant conditions than does a course consisting more largely of lecture or class room work.

Cambridge, Mass.

Growth of the Artificial Silk Industry

Artificial silk, which a few years ago was looked upon as a novelty which provoked smiles in the trade, is growing continually in favor and has become a recognized part of the silk industry. Mr. Monges, a clerk in the American Consulate at Lyons, has compiled some history and statistics on the subject. The world's production of artificial silk was 2,000,000 kilos (about 4,420,000 lb.) in 1902, and the figures increased to 8,000,000 (about 17,680,000 lb.) in 1914. Germany is said to be producing about 5,000 kilos (about 11,000 lb.) daily, and France will be producing about 4,000 kilos (about 8,800 lb.) daily when her machinery has been put in order. The total production for 1919 is not given, but it is well known to have been far below the demand.

It was in 1885 that Audemars, of Lausanne, Switzerland, filed a patent on a vegetable fiber for use in incandescent lamps. In 1884 Comte de Chardonnet discovered the collodion thread which he aspired to place alongside of silk in the textile world. But not until 1895 was it possible for the company which he founded to put on the market a thread which was denitrated and consequently less inflammable. Up to 1903 the new industry, interesting though it was, was not seriously regarded in the industrial world, but rather was considered in the light of an interesting novelty. In that year, however, the Société de la Viscose put on the market the artificial silk which until recently has been the last word in artificial textiles.

On account of the substance which it employs (wood), the new industry has been enabled to adapt itself to all climes and is today in full swing in Belgium, Switzerland, Hungary, Poland, Germany, Russia, Italy, Japan and the United States.

At Lyons a renewed impetus was given recently to the use of chemical textiles by the invention of an entirely new process, the product of which is called silk cellulose. This new form of cloth is claimed to possess a brilliancy comparable to that of silk schappe. It has a remarkable solidity and durability, a touch similar to that of silk, and it is impervious to water. A big factory for the production of the new textile is projected for the Lyons district.

There are five kinds of artificial silk—nitrated silks, collodion silks, the viscose silks, the acetate silks and the gelatine silks.

It is to be noted that the increasing activity of the artificial textile industry, instead of coming into competition with that of the natural silk, coincides with and supplements the growth of the latter. The difficulty experienced by natural silk weavers in providing sufficient material, together with the top prices the natural silk commands, furnishes proof that natural silk is more than ever in demand and has nothing to fear from what many be called a "distant" competitor.—*The Review*, April 1, 1920.

Physical Properties in Rolled Rifle Barrels

By F. L. Moister *

THE specifications for barrels for U. S. Rifle Model 1917 provide for steel of the following chemical and physical properties:

Carbon	0.45 to 0.55
Manganese	1.10 to 1.35
Silicon	0.20 to 0.30
Phosphorus (max.)	0.05
Sulphur (max.)	0.05
Elastic Limit, lb. per sq.in. (min.)	70,000
Tensile Strength, lb per sq. in. (min.)	100,000
Per Cent Elongation in 2 in, (min.)	15
Per Cent Reduction of Area (min.)	30

Barrels made by the Remington Arms Co. were rolled from a 1½-in. round billet and were not subjected to further heat treatment. It was therefore

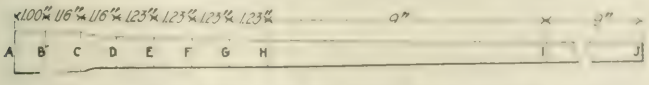

FIG. 1. ROLLED GUN BARREL FOR MODEL 1917 MAGAZINE RIFLE

necessary to obtain the specified physical properties by rolling.

The steel rolled into barrels at ordinary temperatures of hot-working will have elastic limits of about 60,000 lb. The additional 10,000 lb. must be imparted by rolling at low temperatures, but not low enough to reduce the ductility below requirements. The rolling temperatures ranged from 1,200 deg. F. for the lower to 1,260 deg. F. for the highest carbons (650 to 680 deg. C.).

The rolls are designed to finish a barrel in eleven passes. The barrel is an eccentric product, large at the butt and small at the muzzle, but not having an even taper. The rolling reductions are shown in Fig. 1, and also in the accompanying table.

Section	Diameter In.	Area Sq. In.	Per Cent Reduction
Billet*	1.500	1.767	.....
A	1.400	1.539	12.8
B	1.400	1.539	12.8
C	1.300	1.410	20.2
D	1.060	.802	49.5
E	.982	.737	57.0
F	.905	.643	63.6
G	.878	.605	66.9
H	.850	.567	67.9
I	.800	.503	71.4
J	.750	.442	75.0

*Original billet 1⅛ in round, 9.70 to 10.27 in. long.

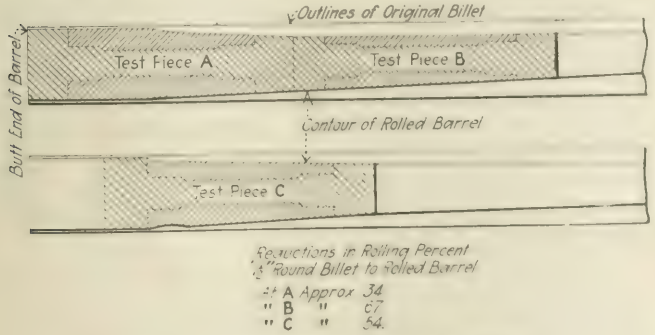

FIG. 2. LOCATION OF TEST PIECES

Consideration indicates that:

First, the finishing temperature varies in different parts of the barrel in proportion to the varying reductions in rolling.

Second, the physical characteristics of the steel vary in proportion to the variations in finishing temperature and reductions in rolling.

Third, the lowest elastic limit and tensile strength will be found in that portion in which rolling reductions are the least and in consequence the finishing temperatures the highest.

Ten billets from the same heat of steel were heated in the same furnace to 1,250 deg. F. (678 deg. C.) and were rolled into barrels on the same mill so as to equalize heating and rolling conditions as far as possible. The finishing temperatures were not determined, but the surface color indicated a range from about 1,000 at the butt to 850 at muzzle (540 to 450 deg. C.).

Three sets of five tensile tests each were taken from points in the barrel to represent the least, greatest and intermediate reductions numbered "A," "B" and "C." Series "A" had its center of gage length as near the extreme butt end as practicable, and series "B" adjoined "A" from same barrels. Series "C" was taken from five other barrels with 1½ in. discarded from butt. Test piece was then cut from as near the butt end as practicable.

Fig. 2 shows the location and methods of cutting these test bars.

Results of the tests, shown graphically in Fig. 3, follow the theory that as reductions increase and

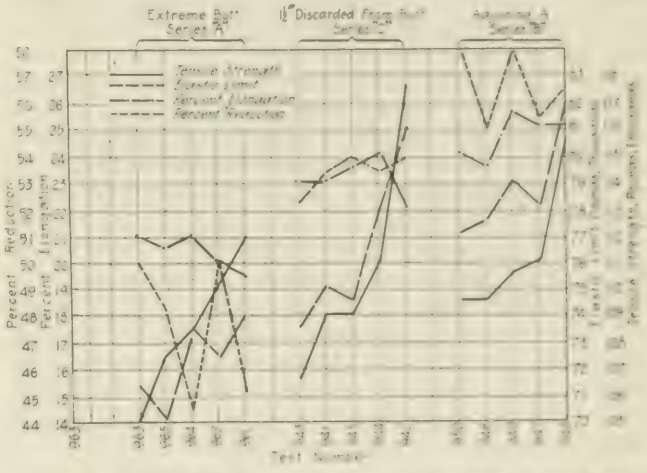

FIG. 3. GRAPHIC REPRODUCTION OF TEST RESULTS

temperatures decrease the tensile strength and elastic limit are increased proportionately. Thus the lowest results were obtained in the "A" series, the highest results were obtained in the "B" series, and intermediate results were obtained in series "C."

Series "A" gets the least reduction in rolling and is finished at the highest temperatures; "B" gets the most reduction in rolling and is finished at lowest temperatures, while "C" gets intermediate reduction in rolling and finishing temperature.

The character of the fractures closely followed the difference in tensile strength. All "A" fractures were flat, slightly lipped, and showed faint radial lines. "B" fractures were semi-flat, and deeply lipped, with radial lines very pronounced. In one piece these lines extended entirely through the section like a split or seam. "C" fractures were semi-flat, lipped more than "A" but not as deep as "B," and the radial lines pronounced, but not as much as "B."

As the radial lines or fissures in all the tests become

* Engineer of Tests at the Eddystone Rifle Plant for U. S. Ordnance Department.

more pronounced as reductions in rolling increase and finishing temperatures decrease, this fact indicates that if the finishing temperatures should be carried low enough the structure would be completely broken down.

Radial lines invariably show in the fractured test piece if rupture occurs toward the muzzle end, i. e., the point of greatest reduction. They never show in the test of an annealed barrel. These radial lines are planes of weakness, produced by pressure in rolling at low temperatures, developed into visibility by pulling in the testing machine, but entirely removed by annealing.

The apparent loss in elongation in series "A" over "B" and "C" is due to fractures occurring outside the middle third of the gage length in all cases, invariably toward the butt pop mark, the weakest portion. In "B" and "C" fractures occurred in the middle third.

Tests were made on an Olsen 100,000-lb. testing machine, working with a speed of cross-head up to elastic limits equal to 0.048 in. per minute. Elastic limits were taken by a Berry strain gage.

The Magnesite Industry in 1919

THE production of magnesite in the United States in 1919 fell off about 30 per cent, but was nevertheless greater than in any year prior to 1917. F. McN. Hamilton, state mineralogist, estimates that California produced 42,000 tons of crude magnesite, or about one-half the production in 1918. According to R. W. Stone, of the U. S. Geological Survey, Department of the Interior, producers in the State of Washington shipped about 55,000 tons of dead-burned magnesite, which is equivalent to about 120,000 tons of crude magnesite, or 20 per cent less than in 1918. The output of crude magnesite in the country in 1919 was therefore about 162,000 tons. The material shipped from the State of Washington went to manufacturers of refractory wares and to steel mills east of Mississippi River, except about 500 tons that was distributed in Montana, Washington, California and Texas. About three-quarters of the California material was calcined and used in the plastic trade and the remainder was natural ferromagnesite used for making refractory materials.

Production Is Satisfactory

The large production indicated should be satisfactory and encouraging to the domestic producers, for even as late as June, 1919, it was expected that receipts of foreign magnesite would practically terminate the domestic industry. The imports, however, were not received as expected, and the demand for magnesite for refractory and plastic wares had to be supplied from domestic sources.

The Northwest Magnesite Co., of Chewelah, Wash., was the largest producer in the United States and made some shipments during each month in the year. Its shipments were smallest in May and June, but increased rather steadily to the end of the year, and are still large. The American Mineral Production Co., of Valley, Wash., sold its output crude to the Northwest Magnesite Co., whose quarries are near by. The Western Materials Co. took over the Double Eagle quarry, formerly operated by the Valley Magnesite Co., at Valley, Wash., and became a new producer in the state.

At the end of 1919 the principal producers in California were the Porterville Magnesite Co. and the Tulare Mining Co., at Porterville; the Western Magnesite Development Co., whose mine is on Red Mountain in Santa Clara County; and the White Rock mine, in Napa County. Smaller operations in California were in progress on the property of the Dinuba Magnesite Co., Tulare County; the Gustine Magnesite Co., Santa Clara County; Sinclair & Ferguson, Fresno County; and possibly one or two others.

Imports

The imports of magnesite in 1919, reported by the Bureau of Foreign and Domestic Commerce, comprised 6,381 short tons of crude magnesite, valued at $103,311, and 9,471 short tons of calcined magnesite, valued at $270,721, or a total value of $374,032. These imports came from the following countries:

	Short Tons	Value
Austria-Hungary	2,650	$64,933
Italy	2,416	62,753
Germany	34	2,023
England	29	4,849
Scotland	94	9,369
Canada	8,066	216,605
Mexico	2,563	13,500
	15,852	374,032

Presumably the material reported from Italy came originally from Austria-Hungary, and that from Mexico came from Santa Margarita Island and was calcined near San Diego. The imports in 1919, which amounted to less than 16,000 tons, were very small in comparison with those of former years. Grecian magnesite was not entered in 1919, and it is understood that none is likely to be imported for some time to come. The California magnesite must therefore continue to be used for the manufacture of Sorel cement, and as the value of this material for floors and for stucco on exterior walls becomes more widely recognized it would seem that some of the California deposits could be operated continuously and with profit. Unless the imports of magnesite suitable for making refractory material increase greatly, the domestic material suitable for refractory purposes —that is, the Washington magnesite and that from the White Rock mine in California—will continue to be used by domestic consumers, so that a fairly good year may be predicted for 1920.—*U. S. Geological Survey, Press Bulletin.*

India's 1919-20 Sugar Crop

The Indian Department of Statistics has issued its final memorandum on the sugar-cane crop of 1919-20, its figures being based on reports received from provinces containing 99 per cent of the total area under sugar cane in British India. Of the Indian states, estimates are furnished by Baroda and the states in Bombay Presidency. Estimates for the Orissa and Chota Nagpur Feudatory states have for the first time been received this year.

The total area shown is estimated at 2,667,000 acres, as against 2,884,000 acres in 1918-19, or a decrease of 7 per cent. The total yield of raw sugar (gur) is estimated at 3,001,000 tons, against 2,370,000 tons last year, or an increase of 27 per cent. The season has, on the whole, been favorable for the crop.

In addition to the areas for which particulars are given above, the crop is grown on a very small scale in certain other tracts in British India, the average area of which for the last five years has been about 25,000 acres, with an estimated production of 28,000 tons.

Manufacture of Potassium Permanganate

Generalizations With Details Obtained From Plant Operation — Chemistry of the Sodium Manganate Process — Dissolving and Chlorinating —Potash Crystallization — Research Possibilities

BY RAYMOND B. STRINGFIELD*

DURING the war, several plants were constructed in southern California to supply the demand for permanganates, and the total tonnage produced was very considerable. No data, however, were available as to either scientific or operating details, and in consequence each plant had to work out its own salvation. Pressure of production necessarily greatly interfered with research, and cessation of hostilities, with the accompanying slump in the permanganate market, found many troubles still unsolved, and one by one the plants ceased operations. The interesting economic feature, however, is that no two plants had the same troubles, and had their combined knowledge been pooled the probabilities are that some if not all of the plants would still be operating profitably.

While potassium permanganate may be obtained in several different ways,[1] the sodium manganate process is the one which has been chiefly used in this country. The literature on the production of permanganate is scanty enough, and as practically no details of actual commercial operations have been published in English, it is hoped that the following notes taken from the author's experience with the industry in southern California will be welcome.

CHEMISTRY OF THE PROCESS

The sodium manganate process for the production of potassium permanganate may be divided into four main steps. Finely ground manganese ore and caustic soda, either with or without sodium nitrate as an oxidizer, are mixed and heated, either in a reverberatory furnace or a shallow iron pan, to form green sodium manganate.

$$MnO_2 + 2NaOH + O = Na_2MnO_4 + H_2O$$

This product is ground, dissolved in water, and the solution treated with chlorine and either sulphuric acid or carbon dioxide to convert the sodium manganate to sodium permanganate.

$$2Na_2MnO_4 + Cl_2 = 2NaMnO_4 + 2NaCl$$

If no chlorine is used, the reaction

$$3Na_2MnO_4 + 2H_2SO_4 = 2NaMnO_4 + 2Na_2SO_4 + MnO_2 + H_2O$$

takes place, with the formation of only two-thirds the possible amount of permanganate and the precipitation of manganese dioxide. With the use of chlorine, the function of sulphuric acid or carbon dioxide is chiefly to neutralize the excess caustic soda, reducing the alkalinity, thereby allowing the more complete reversion of the manganate to permanganate.

The sodium permanganate liquor is freed from any manganese "mud."

The liquor is evaporated until the bulk of other salts present have crystallized out. The theoretical amount of potassium salt is then added, and the solution allowed to cool, potassium permanganate crystallizing out.

$$NaMnO_4 + KCl = KMnO_4 + NaCl$$

In the following description, the operation is not strictly that of any one plant, but details are combined from several plants in southern California.

FURNACES

The most important step in the process for making permanganate is the furnace reaction. Using caustic soda, equilibrium is reached in the reaction at a lower percentage of manganate than when potash is used,[2] but a considerable excess of alkali is necessary in either case, and economic conditions in this country favor the use of soda. Impurities in the ore affect the process in several ways. The presence of a small quantity of iron in the ore is beneficial, the reaction going slightly further toward completion, the iron perhaps acting as an oxygen carrier. Silica and alumina are detrimental, passing into solution later as sodium silicate and aluminate, their subsequent removal being an occasional source of trouble.

Although it is probable that further development would have been the roasting of the charge in comparatively thin layers in mechanically rabbled furnaces at a temperature below fusion, and with only air oxidation, the furnace operated most successfully was a gas-fired reverberatory furnace of the type shown in Fig. 1, operating at 980 deg. C. This furnace was built double, a crew of two men per shift handling the mixing, loading, rabbling and unloading for both furnaces.

Incoming manganese ore was passed through a Blake crusher, and then through a Herman ball mill, using 3-in. iron balls, the 80-mesh product being sent to storage. On account of inadequate grinding facilities, ground caustic soda was purchased in barrels. Sodium nitrate was delivered in 200-lb. (90.7-kg.) sacks.

The manganese oxides, "mud," recovered from the process were air dried on a cement floor, and returned to be used in a fresh mix.

The standard batch consisted of 325 lb. caustic soda, 225 lb. sodium nitrate and 350 lb. manganese ore (147.5, 102.1 and 158.2 kg. respectively). This was mixed in a small concrete mixer and loaded into the furnace with wheelbarrows, through charge holes in the top. It was then spread out with long-handled rakes, made from 4 x 6-in. (10.2 x 15.25-cm.) steel plates on 1-in. pipe,

[1]For electrolytic methods see CHEM. & MET. ENG., vol. [illegible], p. 387, and vol. 21, p. 680 (1919).

[2]For the excellent work of [illegible], Mellor and Russell, J. Soc. Chem. Ind., vol. 14, p. [illegible] (1895).

and as it fused was mixed frequently. When well fused, the mass was thoroughly stirred with compressed air by plunging a 1-in. (2.5-cm.) pipe on the end of an air hose into various parts of the charge. This was repeated just before the furnace was discharged, and had the effect of increasing the percentage of sodium manganate about 1.5 per cent, and of leaving the mass spongy and much easier to grind. The charge was withdrawn by raking through the side discharge holes into wheelbarrows, from which it was spread on a brick floor to cool before grinding. Under normal conditions, eight charges could be handled in one furnace in twenty-four hours, making sixteen for the double furnace. On the charge given above, the average recovery from the furnace as crude green sodium manganate was 72 per cent of the weight of the raw charge. The "green" averaged 25 per cent sodium manganate, which is comparable to Australian practice.[3]

FIG. 1. FURNACE FOR SODIUM MANGANATE, 12 x 18 FT.

Under any operating conditions obtainable, the "green" was found to contain much sodium manganite, which decomposed on dissolving, throwing down a brown "mud," a mixture of manganese oxides. It was found that this "mud" could be air dried and worked into a fresh batch without lowering the quality of the "green." On account of the large amount of water in the "mud" it was not used alone, the mix being 325 lb. caustic soda, 200 lb. sodium nitrate, 250 lb. manganese ore, and 200 lb. air dried manganese "mud" (147.5, 90.7, 113.3 and 90.7 kg. respectively).

Dissolving and Chlorinating

The green manganate was passed through the same Blake crusher used for manganese ore, then through another Herman ball mill. The ground product was fed into a 700-gal. (2,650-l.) mechanically agitated dissolver, until the solution reached a specific gravity of 1.18, corresponding usually to the equivalent of 4.4 per cent $KMnO_4$. A greater density than this did not permit settling of the precipitated "mud." The liquor used for dissolving was the weak solution from the "mud" washing, carrying about 1.0 per cent $KMnO_4$. Into this dissolver, chlorine gas was run in the proportion of 1 lb. to every 4.45 lb. (0.45 to 2.01 kg.) $KMnO_4$ in solution, giving from 55 to 60 lb. (24.9 to 27.2 kg.) per batch. Two chlorine cylinders were mounted on platform scales and the gas introduced through several small holes in a pipe in the bottom of the dissolver. No trouble was had with the chlorine, except that the evaporation would cause cooling, and it was necessary in cold weather to turn the steam hose on the cylinders to melt off the ice, and increase the pressure of the chlorine.

From the dissolver, the muddy liquor was run either to a sulphating tank, Fig. 2, where strong sulphuric acid was added, or to a carbonation tower, where it was treated with carbon dioxide gas. In either case, the alkalinity of the solution was reduced to less than 1.0 per cent free NaOH, this point being easily controlled, with a little experience, by the color of the liquor, the green of the manganate changing to the full permanganate color at about 1.5 per cent alkalinity. The effect of the chlorine is apparently to form hypochlorite, which remains as such until the alkalinity is reduced, when it oxidizes the manganate to permanagate. The chlorinated liquor should be neutralized as soon as possible, and should not be exposed to the sunlight on account of the decomposition of hypochlorite and evolution of oxygen. The possibilities of electrolytic oxidation of the manganate in a suitab'y designed cell are very interesting.

The sulphated liquor was run to one of a series of four settling tanks, from which, after the mud had settled, it was decanted to a fifth tank, and the clear liquor from the top of this tank run over a weir to a "soda liquor storage." Both steel and concrete were found to be suitable for storage, little corrosion taking place as long as the liquor was alkaline, although the concrete was slowly affected. The mud was washed by counter-current decantation, and finally sent to the drying floor. This washing system could very profitably be replaced by a system of Dorr thickeners.

Evaporation

From storage, the "soda liquor" was pumped through a small measuring tank to open steel pans, where it was evaporated by means of steam coils immersed in the liquor, using steam at 60-lb. pressure (4.2 kg. per sq.cm.). As the solution became concentrated, the other salts present, being less soluble than sodium permanganate, were thrown down and were raked from the bottom of the kettles, centrifuged as dry as possible, washed with hot water, and sent to a salt dump. The handling of the salt is influenced considerably by the alkalinity of the liquor. When of proper alkalinity,

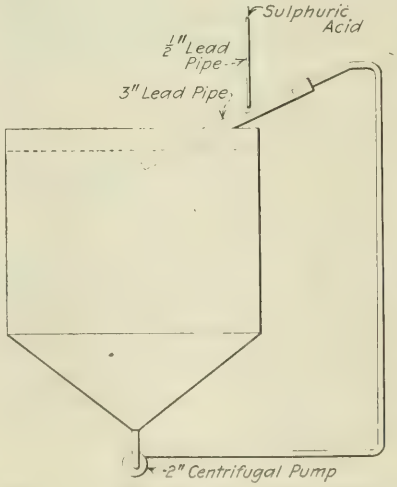

FIG. 2. DETAIL OF SULPHATING TANK

[3] See MET. & CHEM. ENG., vol. 18, p. 546 (1918).

the salt comes down granular, does not scale the coils, and carries most of the silica and alumina in the solution with it. This is especially true when carbonated liquor is used, sulphated liquor carrying a much larger percentage of impurities in solution. If the liquor is excessively alkaline, the salt is very fine, and tends to form hard cakes in the centrifugals, making thorough washing very difficult. On the other hand, too low an alkalinity causes the formation of a hard scale on the coils. As the alkalinity increases, due to concentration, the tendency for the permanganate to revert to manganate increases, and above 5.0 per cent NaOH is liable to cause trouble, the probable equation being:

$$2NaMnO_4 + 2NaOH = 2Na_2MnO_4 + H_2O + O$$

The kettle men were taught to test their own samples by the procedure given later, and when the liquor reached a concentration equivalent to 14.0 per cent potassium permanganate, an amount of potassium sulphate or chloride equivalent to the permanganate present was placed in a wire basket and lowered into the boiling solution. This dissolved rapidly, and the

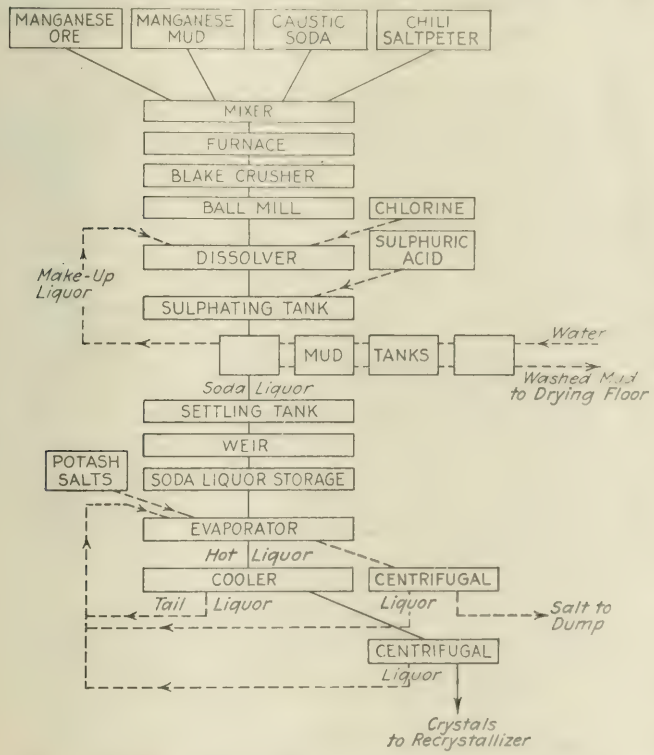

FIG. 3. FLOW SHEET, MANUFACTURE OF PERMANGANATE

solution was then drawn off to shallow iron coolers holding about 400 gal. each. These were supported so as to have free circulation of air, and cooled in four to six hours. After drawing off the cool mother liquor, the crystals were raked into a centrifugal, spun free of liquor, washed with cold water, recrystallized if necessary, dried on screens in a current of warm air, and packed in containers for shipping.

In connection with the crystallization, some interesting solubility effects are observed which deserve much further study. Various mixtures of chlorides, carbonates and sulphates are observed to repress the solubility of permanganate greatly, a mother liquor of 3.0 per cent being common, and 1.0 per cent not uncommon, against a normal solubility of potassium permanganate in pure water of 6.0 to 7.0 per cent. It should also be noted that the true color of potassium permanganate crystals is a brownish black. In former years, the trade has demanded purple crystals. The color was due to a film of decomposed permanganate on the surface. This was caused by the method of drying, and decreased the purity of the crystals 0.2 per cent or more. Most users have now become accustomed to the black crystals, and demand them as the purer product.

Laboratory Control

As mentioned before, a simple method was developed for the analysis of the ordinary permanganate liquors, and the kettle men were taught to make this determination on the soda liquor going to the kettle (to calculate the amount of potash to be added) and on the concentrated "hot liquor." This lessened the labor in the laboratory very materially, and made it possible to run it one shift only without delaying plant operations.

As several of the analytical methods used have not been published, a résumé of these may be of interest.

Permanganate. For purposes of comparison, all results, even on soda liquors, were expressed in terms of potassium permanganate.

On Liquors, Salts and Raw Crystals[1]—Ten c.c. N/10 $FeSO_4$, containing 10 per cent H_2SO_4, was titrated cold with a solution of the unknown permanganate, and results read from a table based on the following: For strong liquors, dilute 10 c.c. to 500 c.c. then

$$\text{per cent } KMnO_4 = \frac{158}{\text{c.c. titration}}$$

For weak liquors, salts and raw crystals, use larger or smaller quantities and correct the result accordingly.

On Green Manganate[1]—Dissolve 5 to 10 g. $NaHCO_3$ in 200 c.c. of water, add 5 g. finely ground manganate, stir until dissolved, dilute to 500 c.c., settle out MnO_2, and titrate with this solution as above. Multiply result from table by 3 to give total yield of permanganate obtainable with complete chlorination, since with this method three molecules of manganate give only two of permanaganate and one of manganese dioxide.

On Potassium Permanganate, U.S.P.—Dissolve 0.750 g. in 200 c.c. hot distilled water in a 400-c.c. beaker, add 5 c.c. 1:1 H_2SO_4, and pipette in very carefully 25 c.c. N oxalic acid. Stir until the MnO, formed is all dissolved, and titrate the excess oxalic acid with N/10 $KMnO_4$. At the same time, run a standard on 0.750 g. of potassium permanganate of known purity. This was prepared by recrystallizing U.S.P. potassium permanganate twice from distilled water, and drying in an air oven at 105 deg. C. On this product, water insoluble was determined on a 10-g. sample, and purity called 100.00 — insol$_{10}$ which was usually over 99.95 per cent. To calculate results, using a slide rule, let t_1 = back titration of standard, and t_2 = back titration of sample. Then purity of the sample =

$$\text{per cent standard} - \left(\frac{t_2 - t_1}{237}\right), \text{ i.e.}$$

$$99.95 - \left(\frac{14.3 - 13.0}{237}\right) = 99.95 - 0.55 = 99.40 \text{ per cent}$$

Duplicate determinations by this method check easily to 0.05 per cent, which is a much greater accuracy than can be obtained by the method of the U.S.P.

[1] Credit for this method belongs to R. W. Poindexter, Jr., of Poindexter & Co., whose suggestions were responsible for its development.

Alkalinity (Causticity due to NaOH).[5] On any strong liquor, dilute 25 c.c. sample to 250 c.c., and of this, take 10 c.c., decolorize with neutral H_2O_2 dropwise, filter with suction on an asbestos Gooch crucible, wash, keeping volume as low as possible, precipitate carbonates and sulphates with 10 c.c. of 10 per cent $BaCl_2$, filter, wash and titrate with N/4 HCl, 1 c.c. = 1.0 per cent NaOH. On weak liquors, H_2O_2 and $BaCl_2$ may be added in same solution and filtered together.

Research Work Needed

Several phases of this process present opportunities for interesting and commercially important research work. Much of this work requires equipment usually found only in a good university laboratory, and in case of an opportunity to engage in such work, the following suggestions are offered.

1. The effect of various proportions, temperatures, impurities and catalyzers on the furnace reaction between caustic soda and manganese ore.
2. Solubilities and phase rule diagrams for mixtures of the chlorides, sulphates, carbonates and permanganates of sodium and potassium.
3. The development of a suitable cell for the electrolytic oxidation of sodium manganate to permanganate.
4. Decomposition of permanganate solutions in the presence of MnO, MnO_2, etc.
5. Best conditions for the elimination of silica and alumina from permanganate solutions.
6. Conditions affecting the reversion of permanganates to manganates in alkaline solutions.

Summary

1. Details for the manufacture of potassium permanganate as carried on in southern California have been given, with analytical methods used in controlling the process.
2. A number of lines of research work are suggested.

Los Angeles, Cal.

[5] Since this method was developed, a similar method has been published by Craig, *J. Soc. Chem. Ind.*, vol. 38, pp. 96-7T (1919).

Wood Pulp Manufacture in Argentina

The utilization of the forestal riches of Misiones Territory, Argentina, for the manufacture of paper pulp is a suggestion that has met with favor among those interested in developing this industry in the country. Adequate means of water transportation is one of the especial advantages emphasized by Trade Commissioner Brady.

This territory, containing about 11,700 square miles, is in the extreme northwest of Argentina, lying between the Rivers Parana and Uruguay, which, in that region, average about fifty miles apart. Since the Parana is navigable for large steamers, water communication can be maintained with Buenos Aires, Montevideo and other ports. Misiones is tropical and heavily wooded, more than 700 varieties of trees having been counted; among these is an abundant tree, called caraguatazol, said to be very well suited for paper pulp.

Although the Territory of Misiones is sparsely settled, it is one of the sections to which immigrants are now turning. A holding, containing 416,800 acres, covered with heavy forests with an abundance of Araucanian pines 65 ft. high, was recently offered for sale at about $2 per acre.

Camphor Production in British Empire

The world's annual requirements and the present practical monopoly of production by Japan of camphor, together with the present high price and increasing demand, have drawn attention to the possibilities of profitable cultivation of camphor in other countries and particularly within the British Empire.

Prof. P. Carmody, F.I.C. (late Director of Agriculture, Trinidad), discusses the situation in the *Times Trade Supplement* of April 10. He points out that refined camphor is now about 2s. ($0.49) per oz. and 23s. 6d. ($5.72) per lb., whereas five years ago it was per pound little over the current price per ounce; and although there are—or have been—great fluctuations, the price may rise further unless increased production is assured.

Commercial camphor, he states, chiefly originates in Formosa, but as "the camphor is obtained there by distillation of the wood the annual destruction of trees must be very considerable, and this may account for the reports of diminishing supplies." It is estimated that 10,000,000 lb. of camphor is required by the world annually. Other present sources are the Fukien Province of China, Shikoku and Kiushiu Islands in Japan, Cochin China, Sumatra, Java and Borneo.

Results Already Obtained in British Colonies

In 1852 the tree was introduced into Ceylon, but little more was done until in 1893 a supply of seeds was obtained from Japan, and 1,000 trees were grown therefrom, from which, in 1901, the yield of solid camphor from fresh prunings was about 1½ per cent. "It is estimated," Prof. Carmody states, "that the yield of prunings (6 to 8 in. long) would amount to 56,000 lb. per acre per annum, and that with camphor at 2s. per lb. the net profit per acre per annum would amount to £74 ($360)." In 1906 there were over 100 acres devoted to camphor growing in Ceylon, but the cultivation was not commercially successful, as less than one ton of crude camphor was harvested.

At the present time experiments, with satisfactory distillation tests, are being carried out in the Federated Malay States, but in Mauritius the oil yielded is not the camphor of commerce.

In 1906, Prof. Carmody states, about fifty trees in Trinidad were transplanted to a better soil, with the result that "the growth has been quite satisfactory and a normal yield of solid camphor has been obtained on distillation," and in Dominica trees "obtained from Trinidad in 1911 have made satisfactory growth and have yielded solid camphor."

Requirements of Successful Cultivation

In the matter of successful cultivation, he advises that "seeds or seedlings from trees that yield no solid camphor must not be used. Stiff clay soils must be avoided. Not more than 300 trees to the acre should be grown in good average soil, or not less than 12 ft. apart in hedgerows, and a sufficient area (from 100 to 500 acres if possible) for economical distillation. When the trees are four or five years old they can be clipped, and thereafter three or four times a year."

Finally, he expresses the opinion that "the successful cultivation of camphor within the Empire is no longer doubtful," and "the reported depletion of native forests offers great inducements for further efforts," particularly in view of present high prices.

Apparatus for the Determination of the Porosity of Metals

By F. K. Bezzenberger and R. A. Wilkins*

In the making of non-ferrous castings for certain purposes, considerable importance is attached to the ability of the castings to hold pressure without leaking. Various tests are made to determine the applicability of a certain alloy or of a certain type of casting to the particular purpose in view. Such tests give isolated results, and offer no workable basis for a comparison of the porosities of various alloys when cast under the same conditions, or of the same alloy when cast by various methods.

An apparatus and method of testing are herein described, which not only afford a basis of comparison in any particular instance, but by which a numerical expression, denoting degree of porosity, can be assigned to any alloy under any conditions of casting. The advantages of such a method are great, not only in that the results obtained can be filed for future reference and comparison, but also because the basis of tests is standardized.

Apparatus

Fig. 1 shows the test casting use. This piece is cast oversize and machined so as to overcome the surface effect. It is of course necessary when comparing different alloys that the same method of casting the test piece be employed in each case, and when the effect of various types of casting is to be determined, that the alloy used and all other conditions be kept constant.

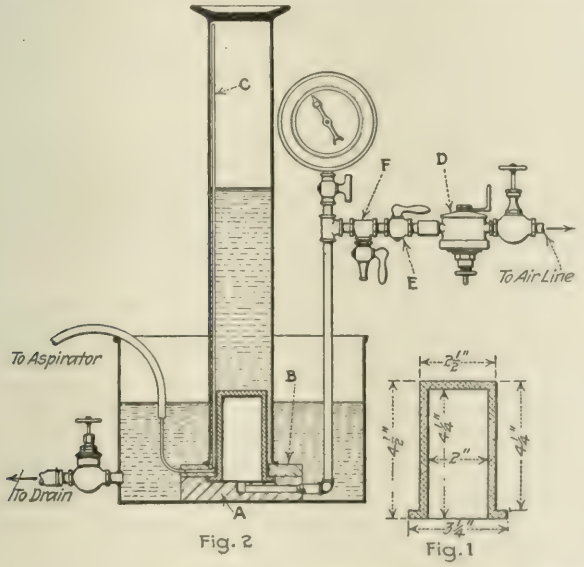

Fig. 2 Fig. 1

APPARATUS FOR THE DETERMINATION OF THE POROSITY OF METALS

Fig. 2 shows the testing apparatus, with the test piece in place. The "test cup" rests on a rubber gasket placed on the base, *A*. This base is made of steel and is drilled so that air may be admitted into the interior of the test piece. The flange, *B*, also made of steel, screws down on the base, holds the test cup in place, and gives an air-tight joint between the cup flange, the rubber gasket and the base. A 2,000-c.c. glass graduate is inverted over the test cup and over the small, rubber-tipped copper tube, *C*. The apparatus rests in a tank partially filled with water. Tube *C* is connected with an aspirator, and is used to remove the air from the graduate, which, of course, is replaced with water. Connections are made, as shown, to a constant-pressure air line. *D* is a reducer, by the use of which any desired pressure is maintained. The cock *E* admits air to the apparatus at the desired pressure. Cock *F* opens the system to the atmosphere, and is used to release the pressure instantly upon completion of the test. A pressure gage is placed in the air line, as shown, and a thermometer is hung in the water tank.

*Research Chemists, Lynite Laboratories of the Aluminum Castings Co.

Method of Testing

Testing procedure is as follows:

The test cup with gasket is placed in position on the base *A*. Flange *B* is then screwed down in place to give a tight joint, and the water tank is filled until the water level is about halfway up the test cup. Cock *E* is opened to test the apparatus for leaks, and the pressure gage is read. If necessary, the reducer is adjusted until the gage indicates the desired pressure. Air is then shut off and exhaust cock *F* opened until the pressure is reduced to atmospheric, and then closed. The glass graduate is then placed in position, and filled with water by means of an aspirator connected to the tube *C*. The apparatus is now ready for the test proper.

The cock *E* is opened at an observed time, and air, leaking through the casting, is collected in the graduate, When the volume of gas collected is sufficient to be read easily, the cock *E* is closed, cock *F* opened, and the time observed. These three operations should be simultaneous. It is well to collect 500 to 1,000 c.c. of air before stopping the test, as the relative error decreases as the volume increases. The difference in level between the water in the graduate and in the tank is measured, and the temperature of the water observed. The test is then complete, when the following data should have been taken:

1. Volume of gas collected.
2. Pressure of air used.
3. Difference in water levels.
4. Time of test.
5. Temperature of water.
6. Barometric pressure.

Calculation of Results

The measure of porosity, called *K*, is equal, numerically, to the number of c.c. of gas, under standard conditions, leaking through the standard test cup per minute per atmosphere of pressure, and is calculated from the formula:

$$K = V \times \frac{273}{Ta} \qquad B - Vp \qquad \frac{H}{13.6} \times \frac{1}{Tm \times Pa}$$

The literal quantities have the following meaning:

V = volume of gas collected, in c.c.
Ta = absolute temperature of water, in deg. C.
B = barometer, in mm. of mercury
Vp = vapor tension of water at observed temperature, in mm. Hg.
H = difference in water levels, in mm.
Tm = time of rest, in minutes
Pa = pressure used, in atmospheres.

The term Pa is introduced into the formula for the sake of simplifying the unit K. For comparative results, however, Pa should be maintained constant. The proportion $\frac{V}{V_1} = \frac{Pa}{Pa_1}$ although approximate, is not exact.

It is obvious that if so desired, the standard test cups be altered in design to permit of the study of the effect on porosity of thickness and of area exposed.

This apparatus and method of testing have been found very valuable in the study of the properties of various alloys. When castings are being made which are required to hold pressure, the incorporation of this porosity determination as a part of the standard testing practice gives data which are of great value in the maintenance of careful technical control.

Cleveland, Ohio.

Output and Shipments of Chilean Nitrate of Soda

The production of nitrate of soda in Chile during January, 1920, was 4,034,517 quintals of 101.4 lb. each and the exports were 9,039,403 quintals. The figures for the same month in 1919 were 4,276,498 quintals and 1,308,951 quintals, respectively. The exportation of 9,039,403 quintals, or about 409,000 long tons, was the largest in any one month in the history of the nitrate trade. It was brought about through the existence of fair stocks on the coast ready for shipment and the arrival of sufficient tonnage to load that quantity. It will not be possible to maintain shipments at that figure constantly owing to the inability of the railroads connecting the elaborating plants in the interior with the ports to transport that quantity regularly.

It is reported that the Asociacion de Productores del Salitre (Nitrate Producers' Association), which controls the sale of most of the nitrate produced, has recently received orders from Europe, and especially from Great Britain, for large quantities of nitrate for delivery before the end of 1920, the totals amounting to over a million tons. Prices are at present in the neighborhood of 15 shillings f.a.s.

The German steamers which were in Chilean ports during the war are being utilized to carry nitrate to Europe. Several have sailed, and three of those which had their machinery disabled are now being loaded with nitrate for Europe. These vessels are to be towed to destination by tugs sent out from Europe for that purpose. The use of the German steamers and sailing vessels will greatly facilitate the movement of the large quantities of nitrate which are now so urgently desired in Europe.

The large shipments of nitrate are reducing the stocks at the oficinas in the pampa, though there is still sufficient quantity to supply what is needed for exportation for several months. In view of the increased demand, five oficinas which were closed down for some time are preparing to start operation soon and are advertising for employees.

Forecast of India's 1919-20 Oilseed Crop

The March forecast of India's winter oilseed (rape, mustard and linseed) crop of the 1919-20 season places the area under rape and mustard at 3,563,000 acres, against 2,964,000 for 1918-19; and that under linseed at 2,323,000 acres, against 1,890,000 acres last year. The condition of this season's crops is, on the whole, considered good.

Legal Notes

By Wellington Gustin

The Chute Process for the Manufacture of Wood Alcohol Valid

In a recent suit for infringement instituted by Harry O. Chute against the Wisconsin Chemical Co., the action was based on claims 1, 5, 6 and 10 of the Chute patent, No. 824,906, for an improvement in the process of making wood alcohol, issued July 3, 1906.

These four claims of the patent are more or less typical of the six other claims of the patent, and are herewith given:

"1. The process of preparing wood alcohol from crude pyroligneous acid, which consists in distilling from said acid a concentrated distillate of between 10 and 25 per cent alcoholic content and of acid nature, allowing said distillate to stand to permit separation of impurities, and decanting off the clear liquid.

"1. The process of preparing wood alcohol from crude pyroligneous acid, which consists in distilling from said acid a concentrated distillate of between 10 and 25 per cent alcoholic content and of acid nature, allowing said distillate to stand to permit separation of impurities, decanting off the clear liquid, adding thereto an excess of alkali, decanting and refractionating the decanting liquid to produce perfectly miscible alcohol of above 80 per cent.

"6. The process of preparing wood alcohol from crude pyroligneous acid, which consists in distilling from acid an acid product of an alcoholic strength wherein oily impurities are insoluble, allowing the same to stand to permit separation of such impurities, and decanting off the clear liquid.

"10. The process of preparing wood alcohol from crude pyroligneous acid, which consists in distilling from such acid an acid product of an alcoholic strength wherein oily impurities are insoluble, allowing the same to stand to permit separation of such impurities, decanting off the clear liquid, adding an excess of alkali, decanting away from the resinous deposit formed, and refractionating the decanted liquid to form a strong alcohol of above 80 per cent and perfectly miscible with water."

Court Holds the Chute Patent Is Merely an Improvement of an Old Process

These claims were held valid and infringed in the United States District Court, and the chemical company attacked the decree of this court in its appeal, relying on alleged invalidity and non-infringement of the Chute patent. In passing on the questions involved, the United States Circuit Court of Appeals, Seventh Circuit, sets out Chute's method. The making of alcohol, it remarks, from wood was old in 1906, therefore the patent relates merely to an improvement of the process.

The pyroligneous acid is obtained from condensing the vapor or smoke from the burning wood to a liquid by means commonly practiced before 1906. This base is used in the Chute method. Chute's problem was to reduce the cost of producing the alcohol from this acid. It contains many ingredients, and it is by retain-

ing some and eliminating others that manufacturers are enabled to produce a merchantable wood alcohol, that is, an alcohol of at least 82 per cent strength and miscible with water. Chute claims to have reduced the cost by eliminating some of the steps previously taken. By his first step he obtained a distillate with a greater alcoholic strength than was formerly sought. By his third step he used an "excess of lime" to (*a*) neutralize the acid and (*b*) remove the resinous ingredient. He describes this step in his specification, as follows:

Practical Results Obtained by the Use of an Excess of Lime

"Therefore, after decanting the alcohol from the separated oily bodies, I add an excess of an alkali, as lime. Reaction soon sets in, as is shown by the development of yellow color, the familiar color known and carefully avoided in working with pyroligneous acid as an evidence of overliming. It is here, however, advantageous and not detrimental. As the reaction progresses, alkali-resinous matters separate and form a precipitate. These resinous bodies formed by the action of the alkali on the aldehydic and ketonic impurities form a mass of novel and useful characteristics, it being substantially a dye resin, being susceptible of use as a dyestuff, as it stains organic matters bright yellow when properly applied, and also of use as a resin. Being formed from a liquid from which the oily and tarry impurities have been removed by previous treatments, it is substantially pure. I do not claim this material herein specifically, but reserve the right to file a separate application therefor. The spirit decanted from this precipitate will be found much improved in quality, having been freed from these two classes of impurities, and I am therefore enabled to directly rectify in any rectifying continuous column, producing by this one redistillation alcohol of standard 82 per cent strength, but of such purity that it is miscible with water in all proportions and cannot be refractionated into portions 'milking' with water."

What Determines the Validity of a Process Patent

An older process in common use was first to free-treat the pyroligneous acid of tar (alcoholic content then being about 5 per cent) so that it might be thereafter neutralized with lime to make a merchantable acetate. By this method the producer was able to market not only wood alcohol (subsequently obtained) but a byproduct of wood alcohol. But repeated distillations were required before wood alcohol, miscible with water, was thus produced. Although Chute's process loses a valuable byproduct, it is an improvement in the art of making wood alcohol; the advance being in the lessened cost of production. But validity of the process, as a patentable invention, does not depend upon the question of whether the wood alcohol plus the value of the byproduct in combination is greater than the wood alcohol alone. These values may vary.

The validity of the process was attacked because of the prior art as disclosed in an article written by Vincent, a French chemist. In his first distillation, Vincent, using a multiple still, stopped "at the point where the methyl alcohol has all been distilled over." He also says, "A rich alcoholic liquid which abridges later operations is obtained." It was contended that this step is equivalent to the first step in Chute's claim 1, above given, "which consists in distilling from the said acid a concentrated distillate of between 10 and 25 per cent alcohol content and of acid nature." But the court held there was a difference between the Vincent and Chute processes. Vincent's description of his primary distillate failed to set forth the specific statement of the per cent of alcohol in the distillate, and it completely failed to provide for the elimination of oils from the acid distillate, and also failed to describe a process whereby wood alcohol of 82 per cent strength was obtainable by two distillations from a pyroligneous acid base. Even if the first step were fully disclosed by Vincent, anticipation of the process would not appear. For invention is recognized in this process not because of any one step alone, but because "a particular step" is taken in connection with other particular steps. The use of "an excess of lime" is important only as a step taken with and after the first step that resulted in "a distillation of between 10 and 25 per cent alcoholic content and of acid nature."

Now, the validity of a process patent containing several steps cannot be assailed by showing any one of the steps to be old. Even where all the steps are old, anticipation is not established, unless it further appears that the steps (old individually) were previously employed in relation to one another as disclosed in the patent the validity of which is disputed.

Validity of Chute Patent Affirmed

The chemical company further attacked the process patent, contending that the use of the words "excess of lime" in Chute's process is too indefinite and vague to apply. But Chute, while speaking to the public, was addressing himself primarily to those educated in the art under consideration. He was dealing with chemistry and to those familiar with the manufacture of wood alcohol. The court was of the opinion that such a class would have no misunderstanding from the use of the term and would experience no difficulty in following the directions given by Chute. Then the specifications of the process remove any doubt. The purpose of "over-liming," as well as its manifestations, clearly appears in the description, and one skilled in the art may follow the directions with comparative ease.

Therefore the validity of the Chute process was affirmed.

New British Dye

After experiments extending over a period of two years it is reported, says the American Chamber of Commerce in London, that the British Dyestuffs Corporation, Ltd., has now discovered at its Huddersfield laboratories the secret of manufacturing alizarine cyanine green dye on a commercial scale.

This green dye was first discovered in Germany at the works of Bayer & Co. in 1894, and was manufactured exclusively by Germany before the war. The exact chemical details were jealously guarded, and no information was given to chemical associations or allowed to appear in German technical journals.

The special characteristics of the dye are that when applied to wool, chromed or unchromed, fine green shades are produced which remain fast. Since the outbreak of the war, woolen manufacturers have not been able to produce varying shades with the fastness of this dye, which is used particularly for tweeds and ladies' dress goods.

The Vegetable-Oil Industry of Hull

FOR a number of years Hull has been known as one of the largest vegetable-oil centers in Europe. Prior to the war Hamburg, Germany, ranked first and Hull had to be content with second place; but during the war Hull so increased its plants and equipment that it is now without doubt the largest center in Europe and, it is thought, will easily retain the trade and position already established.

The industry was completely under government control until the end of March, 1919. This control was worked with the minimum of inconvenience and there were few complaints. The basis of priority allocations upon which the supplies of oil and cake products were distributed was:

1. The manufacture of edible oils, such as margarine and cooking fats.
2. Soap and candles.
3. Industrial uses, including the manufacture of paint, varnish, oilcloth and linoleum.

The greater part of the oil was used for culinary purposes. Linseed oil could be used for industrial consumption only on condition that it be "split" and the glycerine thus obtained delivered to the government.

The war greatly augmented the importance of the vegetable-oil industry owing to the increased demand for glycerine (for explosives), lubricating oil (castor oil for airplane motors), oil cake for cattle food, and oil for the manufacture of margarine. On account of the shortage of butter in the United Kingdom enormous quantities of margarine have been manufactured. Hull plants now turn out an average of ten tons per week, which is retailed at 26c. a lb., against the 98c. a lb. that is obtained for butter.

Imports and Exports

Prior to the war oil nuts from British West Africa were sent mainly to Holland and Germany for crushing. During the war the government requisitioned the entire output of British West Africa and Egypt, but, notwithstanding, the supply of raw material available did not equal the demand.

In tons the weight of the oilseeds imported in 1919 is 1,148,810, against 722,914 tons in 1918 and 1,229,472 tons in 1913, the increase over 1918 being largely due to heavy recipts of linseed, and the falling off as compared with 1913 being due to the smaller quantity of cotton seed received. Approximately three-fifths of the linseed came from the British East Indies in 1919 and practically all of the rest came from Argentina; 247,342 tons of cotton seed came from Egypt, as against 333,435 tons in 1918, and 170,601 tons from India against nil in 1918. Rapeseed and castor beans were practically all from India.

As already stated, oilseeds were controlled by the government until the end of March, 1919. While under control all material was sold at fixed prices, which were changed at intervals by the government, due notice being given. With de-control in view, the Ministry of Food during March made arrangements with the crushers throughout the United Kingdom to take over at fixed prices all stocks and commitments of seed lying in warehouses in different parts of the country. For a short period business was retarded, though such trade as was effected was done at maximum prices. From this time on prices were very flexible.

In addition to the large quantities of raw materials imported from other countries, the United Kingdom makes large purchases of foreign and unrefined vegetable oils, the imports for the past three years aggregating $33,619,642 for 1917, $56,410,494 for 1918 and $104,720,321 for 1919.

The oils and oilseeds imported into the United Kingdom are not all retained in the country for consumption or for manufacturing into commercial products. A certain proportion is reshipped in the form in which received, though such shipments are of minor importance when contrasted with the total imports. These re-exports in 1917 - 1919 amounted to $14,507,663 for 1917, $980,959 for 1918 and $15,141,466 for 1919.

With de-control came a quick revival of the export trade in British-made vegetable oils, shipments in 1919 being nearly seven times those of 1918. The outstanding feature of the year was the phenomenal gain made by pure linseed oil—$31,818,821.

Trade in Oilseed Cake

The imports of oilseed cake (unsweetened) into the United Kingdom for 1919, as compared with 1918 and 1917, were:

	1917		1918		1919	
Oilseed Cake	Tons	Value	Tons	Value	Tons	Value
Cotton seed	131,898	$10,184,616	2,719	$222,024	198,926	$19,527,303
Linseed	76,860	7,221,073	8,109	800,106	71,252	7,977,386
Rapeseed	616	44,850	.....	.....	190	19,466
Unenumerated	3,518	254,489	.....	.....	7,906	806,457
Total	212,892	$17,705,028	10,828	$1,022,130	278,274	$28,330,612

In 1918, for nearly the whole year, the importation of oilseed cake into the United Kingdom was prohibited in the interest of economy of shipping.

The exports of British-made oilseed cake in 1919 amounted to 5,099 tons, valued at $448,857. The exports in 1918 were only seventy tons, value $7,397; and in 1917, eighty-five tons, value $7,499. There were no re-exports of foreign or colonial cake.

Labor Conditions—Profits—Outlook for 1920

During 1919 labor conditions were anything but good. Although there were no strikes in any of the vegetable-oil mills, there was a general dissatisfaction on the part of the workers. Numerous strikes of dockers and a general strike of the railway employees lasting ten days caused great congestion upon the docks, and the crushers were a number of times practically without seed. Furthermore, they had enormous quantities of oilseed cake in their warehouses which buyers were unable to secure because of a shortage of barges and freight cars. Conditions are now practically normal.

During the first quarter of 1919, while the industry was under government control, the profit to the mills averaged 10 per cent. After control was removed there was considerable speculation, and, as before stated, prices soared. During this period and for the last half of the year profits averaged 25 per cent.

The outlook of the British vegetable-oil industry for 1920 is very promising. A new plant of enormous size, consisting of an extraction mill, chemical laboratory, deodorizing plant, refinery, and margarine, lard and soap factories, is erected by a local company. During January and February 596,939 gal. of linseed oil, valued at $999,770, was invoiced through the Hull consulate for shipment to the United States. Shipments promise to exceed this amount later in the year.

Experimental Briquetting Plant

Briquetting of Fuels and Ores Presents a Series of Problems Which Can Be Solved Satisfactorily Only in a Commercial Size Operating Plant—An Outline of the Briquetting Research Work in the General Briquetting Co.'s Experimental Plant

BY ALBERT L. STILLMAN

OF COURSE it will work—*in the laboratory!* What research man has not encountered skepticism expressed by emphasis on the last three words of the above comment?

It is the laboratory result multiplied in plant design and operation that makes industrial progress. It is not unusual to see an excellent product, painstakingly evolved by the research department, fail in commercial production, not from anybody's fault, but because some unforeseen quirk developed in quantity production.

The science of briquet manufacture, perhaps more than other chemical and metallurgical industries, has many problems still in the experimental or laboratory stage.

The science of briquet manufacture does not confine itself to the conversion of anthracite culm into merchantable fuel, although that problem has indeed held the center of the stage for years. Wherever and whenever a fine material is produced as an incident to operation—a fine material whose return to coarser size would be of benefit—a field is open to this most modern of sciences. Such problems are becoming increasingly numerous in these days of enforced economies. Wherever the blast furnace operates, whether on ferrous or non-ferrous reduction, fine ores and flue dust are a detriment, clogging the blast and slowing down operation. Wherever fuel is sized, whether anthracite or non-coking soft coal, the agglomeration of the fines into domestic size is highly desirable. Wherever a saw or planing mill is operated, the sawdust and planings present a conundrum for salvage. Wherever lathes, drill-presses or milling cutters are shaping metal product, a pile of fine metal turnings or millings develops whose disposition has heretofore proved vexatious to the melter. Fine metal, whether iron, brass, aluminum or what not, whether borings, spinnings, turnings or trimmings, suffers vaporization and oxidation loss in melting not sustained by heavy scrap, and the melting requires much more time and care.

PROGRESS OF BRIQUETTING

There is need for specialized research in briquetting. The field has become wide enough to constitute an engineering specialty. It cannot be said that anyone can at a glance advise a method for returning a low-value fine residue to a high-value larger size—still less the best method. Certain problems in the field are now adequately answered—that is, commercial equipment, thoroughly standardized, has been installed, and has made quantity production at a cost well below the selling figure of the briquetted product. The specific instances cover a wide field. The Ohio Metal Briquetting Co. of Cleveland, Ohio, is making 16 to 20 briquets of steel turnings per minute—the briquets running about 12 to 20 lb. each. The light steel is bought at the market price for machine shop turnings and sold at a premium over the market price for heavy melting steel. The product is bought for open-hearth melting, and the open-hearth operators cannot get enough of them. Anthracite coal fines are being briquetted at many plants; notably that of the Lehigh Coal & Navigation Co., Bamford, Pa. This plant was recently enlarged from 200 to 1,000 tons per day capacity. The Berwind Fuel Co. maintains a highly successful operation at Superior, Wis., where Pocahontas—bituminous—coal is pressed into briquets for the Northwest trade. In Buffalo the Wickwire Steel Co. has installed a large toggle press operating at a capacity of eight tons per hour to briquet the daily production of iron flue dust, while in another part of the city the Buffalo Slag Co. operates a similar layout to briquet the flue dust of the Buffalo Union Furnace.

These installations are mentioned to show the progress of the commercialization of briquetting processes to date. Summarized, we find hard and soft coal, blast-furnace flue dust, certain ores and the light scrap of steel and brass alloys are today being briquetted successfully on a commercial scale, while foreign practice shows in addition peat, lignites, sawdust and the light scrap of iron, aluminum and other metals. Indications are that these latter will shortly enter into commercial operation in the United States.

RESEARCH ON BRIQUETTING

Metallurgists and fuel experts conducting their own briquetting experiments have found a scant bibliography to help them and a paucity of available apparatus and experience. Industry has needed a research laboratory specializing in briquet manufacture for a long time. The General Briquetting Co., with all the European experience in the art readily available, none the less appreciated the necessity of such research to meet the special needs of this continent. A trained personnel, the primary requisite, was carefully acquired. A research laboratory was installed wherein pioneer work on many classes of material was done. This undertaking was simply a chemical and physical laboratory with appliances added for the purpose of experimentation in briquet making. Much of value was accomplished.

Foreign experience was confirmed and added to. New methods were devised successfully. But still no method was available for proving that laboratory results could be realized on a commercial scale. Moreover, in briquet manufacture probably more than in any other field the laboratory product is of superlative excellence. Whatever the material, a closely supervised preliminary treatment by hand, whether mixing, shredding or mastication, coupled with the painstaking molding and pressing on a laboratory hand press results in an ideal product difficult to reproduce commercially on a large

scale. This fact has been made use of by uninitiated and unscrupulous alike, in the production of high-class samples for use in the flotation of stock sales for briquetting plants. Especially has this been true in the coal game. Clearly a laboratory for research in this field should be equipped to demonstrate the feasibility of production on a commercial scale and that too by actual trial.

Briquet Questionnaire

The first and most important question of all in determining the possibility of briquetting any given substance is the difference in value between the briquets and material from which they were made. In the beginning

FIG. 1. INTERIOR OF LABORATORY

of research a definite answer is impossible until a reasonable quantity of briquets have been made, and their use demonstrated by consumption under existing conditions. For instance, it is well to know, if possible, the price per ton one can obtain for coal briquets as opposed to coal dust, before establishing a manufacturing plant. The other questions which a client of a briquetting engineer might ask and reasonably expect an answer are as follows:

1. Can this material be briquetted at all?
2. Can it be briquetted by pressure only, without the use of binder or catalytic agent?
3. If pressure only suffices, what pressure gives the best commercial briquet?
4. What shape and size briquet is best suited to the requirements?
5. If binder is necessary, what kind is most advisable and in what quantity?
6. If catalytic agent or accelerator[1] is necessary, what kind is most advisable and in what quantity?
7. What is the best method of admixing the binder or catalytic?
8. What other preliminary treatment such as grinding, heating, mixing, mastication or combinations of one and all of them will be advisable before the material goes to the press?
9. What type of press is best adapted to the purpose in hand?
10. What scale of operation would be most lucrative?
11. What methods should be adopted for most economical handling of briquetted material?
12. Under what conditions are the briquets to be consumed?
13. What will be the cost of a plant and its elements?
14. What will be the total cost per ton of briquets produced?

[1]By catalytic agent or accelerator is meant a reagent which while possessing in itself no binding or cementing power produces a chemical action in the material which results in cementation. The use of ferrous sulphate and other oxidizing agents in the briquetting of blast-furnace flue dust is a notable example.

Both Experimental and Operating Test Required

For some of these questions the answer can be found in a small laboratory; market condition, supply and demand answer some others without scientific investigation; but for the remainder, and especially for the points 8, 9, 11 and 14, a tonnage run under conditions closely approximating commercial is exceedingly desirable. How to obtain facilities for such "runs" in order to supplement laboratory results without excessive expense was the "meat" of the problem. The obvious answer was the installation of an operating plant making briquets of material whose commercial briquetting was already recognized as a market proposition, yet whose machinery was of sufficient variety to meet, at least approximately, any new requirement.

Accordingly the General Briquetting Co. established in New York City, together with a completely equipped research laboratory, an operating plant which divided its activities between coal briquets for the domestic market and the fabrication of brass and bronze turnings into briquets for remelting.

Briquetting Coal by the Dutch Process

For the manufacture of coal briquets, the method known as the Dutch process, made famous by its success at the Lehigh Coal & Navigation Co.'s plant, was adopted. Coal dust requires a binder. The binder used in this case is a heavy oil residuum of a melting point of 160 deg. F. It is melted and piped to a horizontal

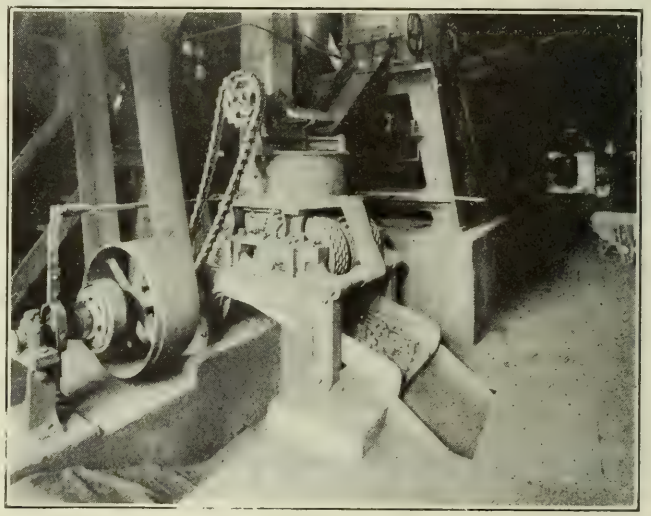

FIG. 2. COAL BRIQUETTING PRESS IN OPERATION

paddle mixer, there meeting a measured flow of dried coal dust, the ratio being about 95 per cent coal and about 5 per cent oil. From the mixer the coal oil flux drops into a great mill, known as the masticator, where heavy rollers grind the oil into the coal to a state, in fact, approaching dryness. From the masticator, the now thoroughly digested flux goes to a roll press, which molds it into 2-oz. eggettes, which are carried over a cooling conveyor to the bins.

The metal briquetting department is designed for the cleansing and briquetting of light brass scrap into clean briquets, 6 in. in diameter, 3 to 5 in. high—ingots in appearance and melting value. The waste metal trade of the East has long recognized the value of briquetted brass as opposed to loose turnings. Briefly, briquets of brass returned to the crucible show a marked decrease in volatilization and oxidation losses, a saving of a great percentage of melting time, and a consequent better control of melting mixtures.

The Vogel system of reclaiming metal, together with the large Ronay metal briquetting press, has been adopted.

In general this process involves the breaking up of the turnings in order that they may be fed to a press without choking the hopper; the removal of machine shop oil, whose presence impairs the strength of the finished briquet; and in the case of brass briquets, the removal of iron.

Installation of the Plant

Specifically at this plant, the installation consists of:

A Gilmore Shredder and Breaker wherein the turnings are broken up from long lengths to less than 5-in. lengths.

A Rockwell Rotary Furnace wherein the broken turnings are submitted to a temperature which has been determined as the proper temperature for burning out oil and waste without impairing the composition of the metal, or annealing the metal, for softening, where necessary.

A Cutler-Hammer Belt Magnetic Separator for the removal of iron filings, and in fact any ferrous admixture.

A Ronay three-stage vertical hydraulic metal briquetting press.

In addition a horizontal hydraulic press has been installed. The press is fulfilling a dual capacity. Where quantities of metal shipments are small and the vertical hydraulic press is at work on a large run, the horizontal hydraulic press works for the operating department, making metal briquets 4 in. in diameter and 3 to 4 in. high. The capacity is about 500 lb. per hour on such work, and the cost is, of course, higher than similar operation in the vertical press. Primarily, however, this press is a laboratory adjunct, and works on research material whenever indications point to a requirement for a pressure briquet approximately of the shape and size for which the mold is adapted. The working pressure can be varied from 3,000 to 20,000 lb. per sq.in.

Supplementing this small press the laboratory carries a small capacity edge runner or grinding mill for breaking or masticating material, and in addition a small rotating gas furnace for purifying purposes with a capacity of 200 lb. an hour.

Procedure of Investigations

Let us assume that this research laboratory is faced with three concrete problems—namely, the briquetting of materials marked A, B, C. Let us further presume that none of these materials has ever been briquetted at all. It is required to determine whether their briquetting could be accomplished with satisfactory commercial results.

The following procedure on the part of the laboratory is characteristic. As no previous experience in briquetting applies to these materials, one and all are tried on the laboratory hand press, using pressure only without admixture, to see whether or not a binder is required.

Let us suppose that material A is a fine metal and gives a good briquet in the hand press at 10,000 lb. pressure, material B, partaking of the nature of the fuel, gives no briquet under pressure without preliminary treatment or admixture, and material C, designated as a byproduct of chemical manufacturing, also fails to give a good briquet with pressure only. At this point the indications are as follows:

Material A. This material will readily make briquets along the approved commercial lines now adopted for metal briquetting. If the laboratory man has 30 or more pounds of this material at hand he makes a briquet on the horizontal hydraulic press. If more material is available, he makes a series of briquets showing results at varying pressures. A good briquet out of this press would show definitely that metal briquetting practice is adapted to the material at hand. When it is reported that the commercial briquetting of this material is possible, the trial is continued on carload quantities. When the carload has been made satisfactorily into briquets on either the vertical or horizontal press, the report furnished thereon, giving the time, power and labor required with the cost of the proper installation, indicates the solution of the problem for briquetting such material on a commercial basis.

Material B. This material presents a problem not quite so simple. The laboratory man tries all the various known commercial binders, still working with

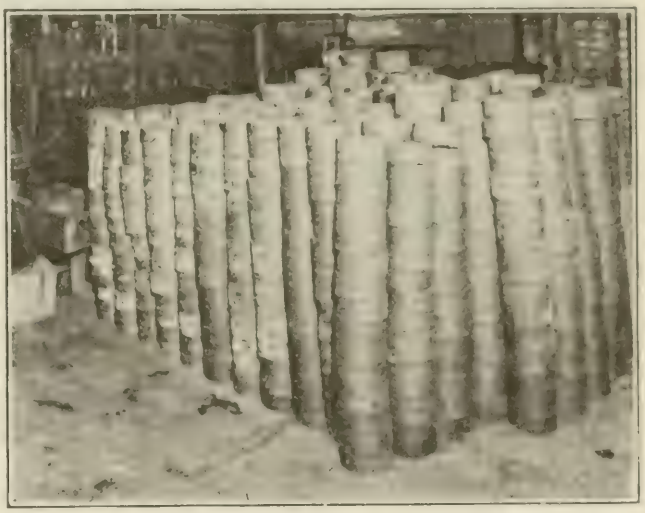

FIG. 3. BRIQUETTED TOBIN BRONZE TURNINGS

laboratory equipment and hand press to find out which binder is best. He further determines the proper treatment—grinding, heating, mastication or the combinations necessary to prepare the materials for pressing. In other words, the best way of mixing the material with its binder. After this mixture is completed short runs are made on the rotary press used in the coal plant turning out 2-oz. eggettes and comparison is made with the product under similar conditions in the horizontal press. If the economic report is satisfactory, work is continued on carload quantity in accordance with the method selected. The report in full on this run will give a correct basis for a commercial installation.

Material C. This material presents an interesting possibility. It is possible that the addition of a cata-

lyzer or accelerator may set up cementing action in the material so that it will bind under pressure. A series of known catalyzers are tried out and briquets made in the hand press. If an action takes place, the situation is probably similar to that of blast-furnace flue dust and the problem will parallel that of the Wickwire Steel Plant at Buffalo. There they briquet eight tons of flue dust an hour on a toggle press—pressure 8,000 lb. per sq.in.—the cementing action being caused by the addition of ½ of 1 per cent ferrous sulphate.

We may presume that one of these catalyzers or accelerators on Material C has shown a result similar to that produced by ferrous sulphate at Wickwire. In the hand press small runs are made by pressures varying from 1,000 to 20,000 lb. per sq.in. to ascertain at what pressure the cementation attains the highest efficiency. On the large Ronay press, as well as

FIG. 4. HORIZONTAL HYDRAULIC BRIQUET PRESS WORKING ON BRASS TURNINGS

the horizontal press, it is possible to vary the pressure within the same ranges. Consequently once the proper pressure is determined a tonnage run can be made in the plant at that pressure. In this case an allowance has to be made for the higher cost of hydraulic operation if the pressure indicated is low; that is, the tonnage run on a carload at the plant with a Ronay or horizontal press would cost more than a commercial installation using the toggle press. However, this deduction is easily ascertained from known practice in other places. The main answer has been obtained; that is, whether or not a merchantable briquet can be produced.

After-Treatment of Briquets

It frequently occurs that questions arise in regard to after-treatment for the purpose of toughening or hardening the briquets after they are produced. In some cases it is preferable, on account of low cost and smelting value, to use an addition of lime to secure binding effect. After-treatment is then often desirable to accelerate the setting of the lime. Such treatment is usually a heat either by direct steam or hot air. For such purposes a small hardening cylinder has been installed which can supply direct flue gas, live steam or super-heated steam to a charge of briquets in the cylinder. This installation has proved particularly useful in investigating the possibilities of ore briquetting.

Range of Usefulness of the Experimental Plant

The plant has already made a number of investigations, some of which are as follows:

Ground Phosphate. For the United States Department of Agriculture. Briquetted successfully in tonnage lots on the rotary press. Preliminary treatment: mastication with small percentage of water.

Carbonized Lignite. For the Lignite Utilization Board of the Dominion of Canada Government. Briquetted successfully in tonnage lots on the rotary press. Preliminary treatment: mixing and mastication with oil residuum binder.

Hard Steel. Briquetted successfully in Ronay press in tonnage lots. Preliminary treatment: annealing in rotary Rockwell furnace.

Hard Bronze. Same as Hard Steel.

Copper Cement. Briquetted successfully in horizontal press without preliminary treatment.

Tin Ore (Cassiterite). Briquetted successfully in roll press. Preliminary treatment: mastication with pitch binder.

Metal Leaf and Paper. Briquetted successfully on horizontal press. Preliminary treatment, low temperature heating in Rockwell furnace.

Complex Copper Ores. Briquetted in rotary press with lime binder. Preliminary treatment: mastication with lime. Final treatment: air-drying 24 hours or steam hardening in cylinder 3½ hours.

Shot Nickel. Briquetted in horizontal press. Preliminary treatment: mixing with sulphite pitch binder in pug mill.

Hardwood Sawdust. For Gas Defense Division, Signal Corps, U. S. A. Briquetted successfully in horizontal press without preliminary treatment.

There has been a host of other investigations, many whose result is still pending. The above serve to show how the supplementing of a laboratory with a commercial plant elastic enough to meet all reasonable requirements is not only desirable but very necessary in this important branch of research. In no other way can the "Fourteen Points of Briquetting" be adequately met.

English Dried-Flowers Industry

In consequence of the shortage during the war of medicinal herbs, an association of women in Suffolk, England, started systematic collection of such plants. From 1916 to 1918 belladonna, henbane and foxglove were the chief herbs handled.

During the year 1919 the demand for medicinal herbs fell off, but in their place arose a request for sweet-smelling herbs and flowers, and it is reported that during the current year collections thereof for the perfumery trade are being organized throughout the county of Suffolk. The new scheme is under the supervision of women botanical experts. It is stated that this rural industry has already resulted in considerable pecuniary benefit to East Anglian villagers, who have been instructed in the proper method of collecting. In April the picking of fresh heads of cowslips commenced, cowslips being used for sachets and pot-pourri as well as a cure for sleeplessness; broom and elder flowers will follow and many others.

A mill at Blackenham purchases the collections and prepares them for the market. The prices per pound at the mill for such dried flowers are: Cowslips (heads only), 2c.; broom flowers, 8c.; elder—heads, 1c., with florets picked off, 5c.; lime, 6c.; mullein and mallow, 8c.; bergamot (flowers without calyx), 12c.; lavender —on stalks, 12c., rubbed off stalks, 61c.; dark-red peony petals, 10c.; dark-red rose petals, 6c.; red field poppy petals, 8c.; mullein leaves, 2c.; raspberry leaves, 1c.; sage, mint, balm, agrimony and woodruff (whole herbs), 2c. Thyme brings 36c. per 14 lb.

Synopsis of Recent Chemical & Metallurgical Literature

Magnetic Properties of Iron Nickel.—In an effort to produce an alloy having higher saturation value than pure iron, for use in construction of electrical machinery, T. D. YENSEN of the Westinghouse E. & M. Co.'s research staff investigated the magnetic properties of very pure iron : nickel alloys made of electrolytic metal in an Arsem furnace.[1] Figs. 1, 2, 3 and 4 give the results of his investigation.

It has been shown by Honda[2] that the properties of the alloys in the neighborhood of 30 per cent nickel are very different after being cooled to liquid air temperature from what they are after being cooled merely to room temperature, and furthermore that this difference is due to the fact that these alloys—in addition to the reversible magnetic transformation points occurring above room temperature—have irreversible transformation points occurring below room temperature.

These transformations have been studied a great deal in recent years, the pioneers in the field being Hopkinson,[3] Le Chatelier,[4] Osmond,[5] Guillaume[6] and Dumas.[7] The alloys investigated by these scientists all contained foreign elements to some extent, particularly carbon and manganese. As a matter of fact, manganese was considered an essential constituent, because without it the alloys could not be forged. It is very unfortunate, however, for the interpretation of the results of the above investigations that these two elements referred to are the ones that affect the transmission points the most. Thus carbon is twenty times as effective as nickel in lowering the transformation points, and manganese, while less effective in this respect than is carbon, still is much more effective than nickel in specific influence. Fig. 5 shows Dumas' results for alloys without C and Mn, and in the region of 30 per cent both revers-

ible and irreversible transformations were found; the latter, however, are lowered materially by a little C, which does not affect the location of the reversible points. Other investigations[8] are grouped in Fig. 6.

After quenching alloys in the 30 per cent region in liquid air, a remarkable change in magnetic properties at room temperatures ensues.

"Its saturation value was increased from 2,700 to 14,600 by cooling to —80 deg. and 17,800 by cooling to —180 deg. Similarly, the electrical resistance was decreased from 82 to 38 and to 32 by the above treatments. It is probable that the change would have gone to completion at —80 deg. if the test piece had been held there sufficiently long and that the irreversible transformation point therefore lies between 0 deg. and —80 deg., thus confirming Dumas' results.

"While only a few points were determined, they are sufficient to demonstrate that the cusp of both curves, after the completion of the transformations, occurs for approximately 34.5 per cent nickel instead of 30 per cent, as the previous investigation would lead one to believe. This points strongly toward the existence of the compond Fe_2Ni, corresponding to 34.6 per cent nickel, suggested by earlier investigators."

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Citric Acid; Calcium Citrate.—Calcium citrate is purified by treatment with sulphur dioxide in the presence of water, the resulting solution of calcium bisulphite and citric acid being then boiled, after removing organic matter by filtration to drive off the sulphur dioxide and re-form the calcium citrate. The precipitated calcium citrate is filtered off, washed, and again subjected to the preceding treatment until sufficiently pure, when it may be decomposed with sulphuric acid to produce citric acid. The sulphur dioxide driven off is available for the treatment of further calcium citrate. When the raw material consists of lime-juice or lemon-juice, it is directly treated with calcium bisulphite, the subsequent treatment being as before (Br. Pat. 136,979 —1919; H. D. GOLDING, J. RASCHEN and UNITED ALKALI Co., Liverpool; Feb. 18, 1920.)

Ammonium Perchlorate. — Ammonium perchlorate is obtained by double decomposition of ammonium sulphate and sodium perchlorate by a process which is stated to be generally applicable whenever one reaction product has a solubility increasing with temperature while the other has a solubility which rises to a maximum and then declines. An initial solution saturated with ammonium perchlorate and sodium sulphate at a temperature below 33 deg. C. is heated to a temperature above 33 deg. C. and ammonium sulphate and sodium perchlorate are added preferably in equivalent quantities so as to cause precipitation of sodium sulphate and saturation with ammonium perchlorate, the higher temperature being such that the ratio dissolved of sodium sulphate to water in the hot solution is the same as the ratio of sodium sulphate to water in the solution at starting. The precipitated sodium sulphate is removed and the solution is cooled to the starting temperature, when an equivalent amount of ammonium perchlorate separates, and the mother-liquor may be used again. It is not necessary for the starting solution to be wholly saturated with sodium sulphate, so long as the ratios above mentioned are equal, nor for the final solution to be wholly saturated with ammonium perchlorate, but these conditions give the best efficiency. An indifferent substance such as a small excess of one of the initial salts, or sulphuric acid, may be added once for all to the reaction mixture. In carrying out the process, the initial salts may be wholly or partly dissolved in separate portions of the initial solution, which portions are then mixed. (Br. Pat. 137,034—1919; L. M. E. WANG, Christiania; Feb. 18, 1920.)

[8] Bureau of Standards, Circular 86, 58 (1916); "Invar and Related Nickel Steels."

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Solder.—There was, during the war, a demand for solders containing a minimum amount of tin, and cadmium was substituted in certain solders with more or less encouraging results. The higher melting point of these solders was to their disadvantage, but for certain uses solders with a relatively high melting point have certain applications where this property is desirable, such as, for example, soldering commutator leads in electric motors. GEORGE P. LUCKEY, of Wilkinsburg, Pa., has found that a solder containing 8½ per cent cadmium and 91½ per cent lead has a relatively high melting point, beginning to melt at 249 deg. C. and completely melting at 280 deg. C. Solder of this composition has a maximum breaking strength, approximately 3,600 lb. for ½-in. round butt-soldered joint. (1,333,666; March 16, 1920; assigned to the Westinghouse Electric & Manufacturing Co.)

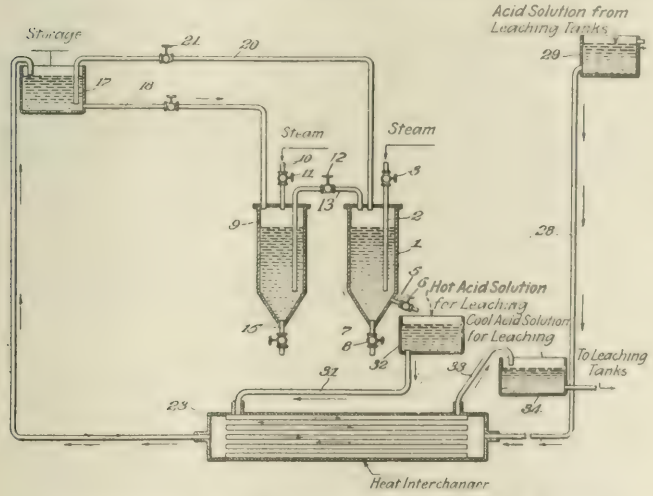
Purification of Zinc Solutions.—Nickel is one of the metals which produces deleterious results when sulphate solutions of zinc are electrolyzed for the recovery of zinc. In practice it is found that to obtain satisfactory results nickel must not be present in excess of one part per million. This element is not removed by the usual method, which consists in agitation with zinc dust at atmospheric temperature. SAMUEL FIELD of London, England, notes that in the presence of copper and at temperature of from 80 to 100 deg. C. zinc fume or blue powder will cause the precipitation of nickel, copper and cadmium and after removing the precipitate, the nickel content of the solution will be reduced to 0.5 part per million or less. (1,337,058; assigned to Metals Extraction Co., Ltd.; April 13, 1920.)

Process for the Extraction and Recovery of Tungsten.—The process consists in crushing the ore, preferably to pass a 120-mesh screen, leaching the comminuted ore with an alkali hydroxide such as caustic soda, filtering and washing the cake, and precipitating the tungsten from the filtrate by means of calcium chloride. Previous to filtering it is desirable to add acetic acid to give a slightly acid reaction to the solution. Suitable apparatus to carry out the process is described. (1,335,277; A. G. DE GOLYER of Ouray and A. E. RUND of Denver, Col.; March 20, 1920.)

Method of and Apparatus for Precipitating Copper From Hot Solutions.—When sulphuric acid is used to dissolve copper from ores or calcines, there usually is obtained a solution which contains iron sulphates. These, if the solution be electrolyzed for the recovery of copper, cause an increase in the amount of power consumed per unit of copper recovered. If the use of the solution be cyclic, the iron salts may accumulate to such an extent as to make uneconomical the continued use of the solution in this manner. Under these circumstances the copper is usually precipitated from the solution by means of iron and the liquor is wasted. This results in a loss of valuable acid. The expense of recovering all of the copper by precipitating on scrap iron is usually prohibitive.

FREDERICK LAIST, of Anaconda, Mont., proposes to precipitate the copper from hot solutions, using sulphur dioxide as the precipitant. It has previously been proposed to precipitate copper by impregnating the solution with sulphur dioxide and heating to a considerable temperature in a closed vessel. This process, while feasible, is not economical, due to the excessive cost of heating the dilute solution. It is desirable in using the process to heat the solution to a high temperature, since as a general rule the higher the temperature to which the solution is heated the greater the percentage of copper precipitated. The improvements proposed that result in a practical and economical process are in the conservation and utilization of the heat remaining in the solution from which the copper has been precipitated.

In the figure is illustrated, diagrammatically, apparatus suitable for carrying out the improved process. The



APPARATUS FOR PRECIPITATING COPPER FROM HOT SOLUTIONS

closed precipitating tank 1 has a steam supply pipe 2, extending into the solution as shown. Near the top of the conical bottom of the tank is a liquor outlet pipe 5. A pipe 7 is provided for the withdrawal of the precipitated metal. The closed preheater 9 has an inlet pipe 10 supplying steam to the upper part of the tank. A pipe 13 connects the upper part of the precipitating tank with the preheating tank, the outlet of the pipe being close to the bottom of tank 9, as shown. The tank is provided with a draw-off pipe 15. A closed storage tank 17 has an outlet (not shown) leading to an SO_2 compressor for the recovery of excess SO_2. This tank is connected near the bottom with the preheating tank 9, by means of a pipe 18. A pipe 20 connects the top of the precipitating tank 1 with the storage tank, the end of the pipe being near the bottom of the storage tank. Below the level of tanks 1 and 9 and the storage tank 17 is a tubular heat-interchanger, 23, of the counter-current type. This is so designed that cold solution from the elevated tank 29 will flow through pipe 28 through tubes in the heat-interchanger and out through pipe 27 to the storage tank. Hot solution from the receptacle 32 flows through pipe 31 around the tubes in the heat-interchanger and out through pipe 33 to the receptacle 34.

The precipitating operation is carried out in the apparatus as follows:

The precipitating tank 1 is filled approximately three-fourths full of the copper-bearing solution from which the copper is to be precipitated, such solution being heated in the manner to be described to about 125 deg. C. From this temperature the heating to about 155 deg. C. is completed by admitting live steam from a boiler through valve 3. Prior to the treatment with live steam SO_2 has been added to the solution. The precipitation having been completed and a final temperature of 155 deg. C. having been attained, the valve 3 is closed and the valve 12 opened, thus releasing the pressure in tank 1 of about 100 lb. per sq.in. and causing the liquid to boil. The steam passes through pipe 13 into the solution contained in tank 9. In about 30 min. an equalization of pressure between tanks 9 and 1 is accomplished and also an approximate equalization of temperature results. What actually happens is that the pressure in tank 1 falls from about 100 lb. to about 30 lb. and the pressure in tank 9 rises from zero to about 30 lb., at the same time the temperature of the liquid in tank 1 falls from 155 deg. C. to about 130 deg. C. while the temperature in tank 9 rises from about 100 to 125 deg. C.

This having been accomplished, valve 12 is closed and valve 21 opened, permitting the steam to flow into the solution contained in tank 17, which has been raised within a few degrees of the boiling point by passage through the heat-interchanger. At the same time the acid liquor in tank 1 falls in temperature to about 100 deg. C. and is allowed to flow into the hot solution receptacle 32 by opening valve 6, whence it flows through the heat-interchanger to receptacle 34 and thence to the leaching plant. The copper which has been precipitated is drawn off by opening valve 8.

Valve 12 is now again opened and at the same time high-pressure steam is admitted through valve 11, forcing solution in tank 9 into tank 1 for treatment. Tank 9 is recharged with boiling solution from tank 17. The acid liquor which is received from the leaching vats into tank 29, in passing through the heat-exchanger, is heated from about 20 to about 90 deg. C. and delivered to tank 17 at this temperature.

In the manner described the process is economical and in certain circumstances to be preferred to the electrolytic method of recovering copper from solutions. The copper recovered is of wire-bar grade. (1,333,985; March 16, 1920.)

Preserving Hydrosulphite Solutions.—Solutions of hydrosulphites used in the indigo dyeing industry decompose rapidly. It is the usual practice to make up a fresh solution each day. PETER MACINTYRE of Clinton, Mass., has found that stock solutions may be kept for several weeks in tanks cooled with ice water. A layer of oil is poured on the surface of the solutions, forming an air-tight seal which prevents oxidation. (1,333,029; March 9, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Sixth National Exposition of Chemical Industries

The National Exposition of Chemical Industries returns this year to the Grand Central Palace in New York, where it will be given during the week of Sept. 20 to 25.

This Exposition, which is the sixth, will be more pretentious this year than ever, there being now engaged space for 358 exhibitors, which is more than in the last Exposition, in Chicago. The growth of this Exposition is remarkable and in a way indicates the growth and development of the chemical industries in America. In 1915 the first Exposition was composed of 83 exhibitors, the second increased to 188, the third to 288, the fourth to 334, and in the fifth, in which the available space was much restricted, exhibitors were held to a minimum of 351. This year another floor has been obtained in the Grand Central Palace, giving four floors, so that exhibitors may not suffer the cramping felt in the last Exposition.

Increased Attendance and Interest

Quite as remarkable as the growth of the Exposition itself is the increased attendance and interest that is shown in the exhibits. To the first Exposition there came 63,000 visitors, to the second there came 80,000 and the number has steadily increased till at the last there were in excess of 111,000 visitors. One who has watched the development of the Exposition and the interest of the visitors can testify to the great improvement in character of representatives the manufacturers have in attendance with their exhibits. The visitors, too, have undergone a change—one of education. The first Exposition brought forth a small following of the idly curious, but in subsequent Expositions a study of those attending has developed the fact that the interest even of the general public is more vital.

Three Sections Planned

This year the Exposition will have three special sections—the Electric Furnace Section, the Fuel Economy Section and a Materials Handling Section. The two latter are new sections. The first will, as its name implies, be one of electric furnace exhibits; the Fuel Economy Section will consist of exhibits of machinery and apparatus, furnaces, producers, stokers and all devices for the economic utilization or more efficient combustion of fuel. The possible exhaustion of our fuel reserves in the not far distant future and the present high cost of fuel make this section of much interest to all industrial plants. The Materials Handling Section will be a series of exhibits of machinery and equipment for the handling of material such as conveying, transporting and elevating. Included in this will be weighing, measuring and power transmission equipment. So important have these mechanical features become for all industrial plants due to the shortage and high wage for man power that an unusual interest is expected in this new section.

The program for the Exposition will have sessions on subjects the phases of which will be developed in the exhibits of these latter two sections. There will be sessions on chemical engineering, for which an elaborate program is planned. Motion pictures will form part of the program, and there will be popular public addresses as well.

Code of Engineering Ethics

A proposed new code of ethics, prepared by a committee of mechanical engineers, but intended to serve as a basis for a code of principles for all engineers, was discussed at the semi-annual meeting of the American Society of Mechanical Engineers, held in St. Louis, May 24 to 27.

The essential feature of the code is its brevity. It is intended to be a brief, positive statement of the professional relations of engineers to the public, to their clients or employers, and to one another.

The committee formulating the code recommended the establishment of a standing committee on professional conduct to interpret it, and also to judge cases of questionable ethical conduct on the part of engineers.

Proposed Code of Ethics

1. The mechanical engineer should be guided in all his relations by the highest principles of honor, of fidelity to his client, and of loyalty to his country.
2. His first duty is to serve the public with his specialized skill. In promoting the welfare of society as a whole he advances his own best interests, as well as those of the whole engineering profession.
3. He should consider the protection of his client's or employer's interests in professional matters his essential obligation, provided these interests do not conflict with the public welfare.
4. He shall refrain from associating himself or continuing to be associated with any enterprise of questionable or illegitimate character.
5. He can honorably accept compensation, financial or otherwise, from only one interested party unless all parties have agreed to his recompense from other interested parties.
6. He must inform his clients of any business connections, interests or circumstances, such as might influence his judgment or the quality of his services to his clients.
7. He must not receive, directly or indirectly, any royalty, gratuity or commission on any patented article or process used in the work upon which he is retained without the consent of his clients or employers.
8. He should satisfy himself before taking over the work of another consulting engineer that good and sufficient reasons exist for making the change.
9. He must base all reports and expert testimony on facts or upon theories founded only on sound engineering principles and experience.
10. He must not regard as his own any information which is not common knowledge or public property, but which he obtained confidentially from a client or while engaged as an employee. He is, however, justified in using such data or information in his own private practice as forming part of his professional experience.
11. He should do everything in his power to prevent sensational, exaggerated or unwarranted statements about engineering work being made through the public press. First descriptions of new inventions, processes, etc., for publication should be furnished only to the engineering societies or to the technical press.
12. He should not advertise in an undignified, sensational or misleading manner, or offer commissions for professional work, or otherwise improperly solicit it.

Nitrate Distribution

Charges being made on the floor of the House that the War Department is putting all possible obstacles in the way of the distribution of a portion of its nitrate reserve for fertilizing purposes were denied categorically by Major J. H. Hunter, who is in charge of the distribution. To set up the machinery to handle the distribution of this material, he states, has required a few days, but every effort has been made to expedite the work.

Since only twenty-four requests have reached the War Department for this fertilizer since the passage of the bill permitting its distribution, it is anticipated that there will be no demand for the entire 100,000 tons for the distribution of which authority has been granted. It is feared that the season has advanced so far that the demand for fertilizer will not be great, although it is pointed out that Chilean nitrate can be used to particular advantage for a considerable period as a top dressing.

Faraday Society Receives Thanks for Its Assistance During the War

At the last meeting of the Faraday Society the president, Sir Robert Hadfield, made public the important part the society had taken in 1916 and 1917 in the movement which led to the formation of the Nitrogen Products Committee. The occasion of the announcement was the receipt of a letter of thanks from Sir Graham Greene, Secretary of the Ministry of Munitions, acknowledging the assistance received from the society and many of its members.

The letter states that arrangements are now on the point of being concluded whereby the synthetic ammonia factory which had been partially erected is to be transformed into a commercial project on a very large scale, and many other fixation schemes are under consideration throughout the Empire. It concludes that the Faraday Society will doubtless consider the objects it had in view, in bringing the nitrogen problem before the Ministry, have been in a great measure achieved.—*The Engineer*, April 23, 1920.

Government Oil Corporation Proposed

Carrying still further the semi-governmental corporation idea, Senator Phelan of California has proposed in a bill the formation of the United States Oil Corporation to develop oil resources in foreign countries. Control of the concern is to be in the hands of nine directors to be appointed by the President. The corporation "may explore, develop, refine, transport and store petroleum and its products." It may form subsidiary corporations and may solicit subscriptions of stock. The majority of the stock must be owned by American citizens, but foreigners may become minority stockholders. Reports as to the activities of the company may be demanded from time to time.

E. I. du Pont de Nemours Buys Varnish Plant

Announcement has been made that E. I. du Pont de Nemours & Co. and the Flint Varnish Co., of Michigan, have purchased the Chicago Varnish Co., of Chicago, Ill. No radical change of organization is contemplated. W. J. Schlinger, vice-president and general manager of the Flint company, will have charge of the two plants.

Phosphate Deposits for Lease

Secretary Payne has approved rules and regulations for the leasing of phosphate deposits in the public lands. About 2,500,000 acres of lands in Wyoming, Idaho, Utah and Montana have been withdrawn from disposition for a number of years awaiting legislation recently enacted by Congress. These regulations will open them to lease in areas not exceeding 2,560 acres each and should add largely to the fertilizer supply of the United States, phosphate forming an important ingredient in commercial fertilizers. Applications for leases are to be filed with the local land offices for transmission to the Secretary of the Interior, and printed copies of the rules and regulations will be available to those officers and to the public as soon as printed.

Status of Paper Makers' Strike

Leaders of Unity of Workers, an independent organization of paper makers, on strike for 70c. per hour, express themselves as being satisfied with the results of the strike so far, and say that they hope to bring out more men in the course of a week. Effort is being made to call out firemen's helpers in all mills, which if successful will seriously handicap operation. Conferences between the Eagle Lodge of Paper Makers, an organized labor group, and manufacturers have reached a point where it is expected that an agreement will be reached on the Buffalo wage scale. However, the American Writing Paper Co., operating sixteen mills, has disagreed with the independent companies on the individual contract and refuses to institute it.

John Crerar Library Moves to New Quarters

The John Crerar Library at Chicago has closed its doors for four months, during which period it will be moved to the new location at Michigan Ave. and Randolph St., opposite the Chicago Public Library. The long period for which the library will be closed works considerable hardship on the technical men of the city, and is due to the fact that Marshall Field & Co., in whose building it has been located, gave peremptory notice that the library could not remain open another day after April 30, the expiration of its lease. This is in spite of the fact that the library has occupied the quarters for over twenty-five years.

New Wood Reduction Plant at Hattiesburg, Miss.

Plans have been made and contract has been signed for a $500,000 wood reduction plant at Hattiesburg, Miss., for the Hercules Powder Co. of Wilmington, Del. Turpentine, pine oil and rosin will be extracted from pine stumps on 100,000 acres of cut-over pine lands. A 100-acre site has been purchased for reduction works and contracts for erecting sixteen plant buildings have been awarded to A. D. Little, Inc., Cambridge, Mass. About $3,000,000 will be the cost of plant and timber land development.

Publishers Plan to Buy Paper Mills

Fear of Government regulation in the control of paper stock has caused the newspapers to try to work out a plan of salvation. To avoid dealing in the spot market, the smaller publishers are devising a plan to buy and operate their own paper mills. Already two mills of combined output of 28,000 tons per year are under negotiation.

May Meeting of the American Section of the Society of Chemical Industry

Friday evening, May 21, Rumford Hall afforded the usual opportunity for the weekly gathering of chemists. On this occasion, the program attracted many men interested in glue and gelatine and industrial heating with gas. Sumner R. Church presided due to the absence of Charles E. Sholes. He stated that he as an industrial chemist was a firm believer in the Society of Chemical Industry. He said it had a peculiar field and the American Section should be built up to at least twice its present membership of 800.

Robert H. Bogue opened the program with a noteworthy paper on "Properties and Constitution of Glues and Gelatines." As this address embodied some of the subject matter which is to be published more elaborately in this journal during July, no attempt will be made to review the paper.

Research Opportunities in Gas Industry

In discussing "Opportunities Offered to Chemical Industry in the Manufacture of Gas," Robert M. Searle suggested some of the problems confronting the gas engineer to which chemical research could be profitably applied. Mr. Searle felt that some of the problems were of such fundamental importance that they were worthy of the life-long attention of trained scientists, and he made an earnest plea for an endowed foundation where the research man's efforts would not be diverted from the main problem by the routine worries of an operating plant.

Even at the present time, there is much to be learned on the distillation of coal in retorts. Other research opportunities are: the recovery of sulphur and ammonia, possibly in the form of ammonium sulphide; the development of a non-clinkering brick less costly than carborundum; desulphurizing spent oxide, possibly though the use of a solvent.

In conclusion, several views of the modern vertical retort plant of the Rochester Gas & Electric Corporation were shown. Although 450 tons of coal is carbonized per day, the labor required is only six workmen and two foremen per shift. By keeping the CO_2 content of the producer gas constant to within 0.1 per cent, the retort temperature does not vary more than 90 deg. F.

Gas as a Fuel for Industrial Heating

The importance of using gas as a fuel for heating in industrial plants was well presented by Dr. Henry O. Loebell. He considered the various fuels in use at the present time, such as coal, coke, crude oil, fuel oil and gas, and pointed out that not only was gas, particularly blue water gas, cheapest but possessed many other advantages. Storage, which takes up a large portion of space in a plant, is reduced to a minimum. Ashes, together with attendant grate troubles and ash-handling apparatus which accompanies the use of coal or coke, is entirely dispensed with. A finer and more accurate control of flame and temperature is possible and products of combustion leave no residue, thus insuring cleaner operation.

He emphasized the importance of flame temperature as well as B.t.u. content and stated that blue gas was the best fuel due to the fact that it burned more intensely, had a greater heat delivery and was actually the most efficient and economical fuel for most uses.

Canada's Pulp Wood Embargo May Cause Retaliation

The passing of laws by Canada forbidding United States paper companies holding leases entitling them to cut timber on crown lands and from exporting the wood unless made into pulp in Canada has imposed considerable hardship upon the paper manufacturers of this country. The purpose of this action is apparently an attempt to keep the foreign pulp and paper industry on its own resources and thereby give Canadian paper industry an added advantage.

Although opinion hostile to a modification of this measure is known to exist, the refusal will mean, as a matter of course, says Senator Underwood, that an attempt to get through Congress an embargo measure directed at Canada will follow.

Canada's newsprint production has increased from 150,000 tons in 1909 to 808,000 tons in 1919, made possible by imports of sulphur and coal from the United States, on which an embargo may be placed.

Position of Norwegian Industry

At the general meeting of the Industrial Federation of Norway, General Director Platou, who opened the meeting with a speech in which he gave interesting information about the situation of Norwegian industries, made the following statement: While in 1885 there were approximately 1,900 factories and works, the number in 1917 was 7,000. The total paid-up capital stock, which in 1913 amounted to approximately 375,000,000 crowns ($100,500,000), had risen to 782,000,000 crowns ($209,576,000) in 1917, and at the close of 1918 to 1,127,000,000 crowns ($302,036,000). Of the total value of imports into Norway, materials imported for manufacture amounted in the years from 1876 to 1880 to approximately 26 per cent and in 1917 to 65 per cent. At the same time the exports of industrial products rose from 11 per cent of the total value of Norwegian goods exported in 1876-1880 to 65 per cent in 1917. The returns that the speaker had obtained from a number of concerns showed that in the years 1913-1918 an average dividend of 8.87 per cent had been paid, which is considerably under what other trades yielded during the period.

Quebec Has $10,000,000 Maple Sugar Crop

The Quebec province maple sugar crop of this year was from one-fourth to one-half as great again as last year's and the value was estimated at $10,000,000. The number of trees tapped showed an increase of 1,000,000. This is a great increase over former years when one takes into consideration the fact that the value of the 1910 crop was estimated at only $1,000,000. The above does not represent the possible yields, however, as anywhere from one-half to two-thirds of the sap is wasted, either by running over from the sap buckets or by the fact that not all the available trees are tapped.

Another World's Fair Proposed

An international exhibition of arts, industries and manufactures, and the products of the soil, mine and sea, to take place in Philadelphia in 1926 to celebrate the 150th anniversary of the signing of the Declaration of Independence, is proposed in a bill which has been introduced by Representative Darrow of Pennsylvania.

Inventions by Government Employees

In reporting favorably to the Senate the bill increasing the force and salaries in the Patent Office, the Committee on Patents added to the bill, as a new section, the bill outlining a procedure for dealing with inventions and patents developed by Government employees in the course of their official duties. The new section is an exact copy of a bill which had passed the Senate previously. It was made a part of the measure to increase the force and salaries in the Patent Office so as to expedite its enactment into law. It is understood that there is no objection to the bill in the House. The reasons for enacting such legislation are set forth by the committee as follows:

> There is no fixed or general policy dealing with inventions and patents developed by Government employees in the course or as a result of their official duties, and consequently no governmental administrative machinery for translating such inventions and patents into actual public service.
>
> In cases where patents are developed by the combined efforts of Government employees and others, difficulties at present arise concerning the administration of the same because of the conflict between the rights of the inventors and those of the United States.
>
> There is no way at present by which patentees in or outside the Government service can dedicate their patents to the public with the assurance that the public will reap the full benefit therefrom, because an invention covered by a patent so dedicated does not interest capital, and because it may be excluded from public use by patents subsequently taken out by others.
>
> Conditions brought about by the war, causing an unprecedented demand for inventions, and the industrial developments and readjustments now following the war, call imperatively for guidance. Also the host of inventions developed during the war in the many Government bureaus and other organizations, primarily for war purposes, but which have a peace application of inestimable value, should be co-ordinated, conserved and translated into industrial use.
>
> There is provided a means aimed to be acceptable to the medical profession of patenting and consequently properly controlling inventions in the field of medicine and surgery, the control of patents by private interests being contrary to the ethics of the medical profession.
>
> It is desirable to have governmental administration of a certain type of patents, not ordinarily attractive to manufacturers, in order to provide production of needed devices or materials for governmental or public purposes.
>
> Provision is made for some remuneration to patentees, to stimulate invention.

The increases in the Patent Office as provided in the bill will call for an increased expenditure of $511,840.

Insectides and Charcoal

The Walnut Growers' Spray Manufacturing Co., a subsidiary of the California Walnut Growers' Association, has completed its new plant at Los Angeles and is now manufacturing several varieties of its "Nicodust" insecticides. These are preparations of nicotine in various strengths combined with other ingredients, to combat the many insect pests which afflict the trees and vegetables of the vicinity.

In connection with this plant the Arthur R. Maas Laboratories have recently finished the erection of equipment to produce poultry charcoal from the many tons of walnut shells which were formerly a waste product. Three tons of charcoal per day is being produced, a ready demand for the product being found among the large poultry ranches of southern California. Tar and creosote are also being recovered from the walnut shells and will be utilized. Harry L. Glaze is responsible for several successful mechanical engineering innovations in this installation.

Decennial Celebration at Forest Products Laboratory

The celebration of the tenth anniversary of the Forest Products Laboratory will be held at Madison, Wis., on July 22 and 23. Present plans call for a two-day program, including addresses by men prominent in science, industry and commerce, inspection of the laboratory, a banquet and various other forms of instruction and entertainment. It is proposed to make a permanent record of this decennial in the form of a souvenir publication to contain all of the addresses and other relevant matters, including the names of those who can permit a permanent record of their operative contributions to be made.

During the ten years of its existence the efforts of the laboratory have been devoted to the development of improved methods and processes for the better utilization of forest products of all kinds, and to the direct assistance of the industries concerned. Among the major lines of endeavor are the following:

Pulp and paper	Grading lumber
Hardwood and softwood distillation	Laminated construction
Preservation of wood	Chemistry of wood
Decay and decay prevention	Boxing, crating, packing
Mechanical properties of wood	Needle and leaf oils
Glues for wood	Ethyl alcohol from wood waste
Kiln drying and air seasoning	Wood finishes
Grading structural timbers	Aircraft parts
	Veneers and plywood
	Steam bending
	Identification of wood
	Microscopy of wood

During the war direct assistance was rendered the War and Navy Departments and various other branches of the Government in the solution of many important problems, particularly in connection with aircraft, gunstocks, artillery wheels, escort wagons, and the boxing and crating of arms and stores for overseas shipment. It was necessary, throughout this period, to abandon all work on the regular peace-time program.

The committee in charge of the program extends a hearty invitation to CHEMICAL & METALLURGICAL ENGINEERING readers to attend the celebration.

Cottonseed Mills Import Peanuts

A 4,000-ton shipment of shelled peanuts from China has arrived at Galveston, Tex. This is the first of a large consignment contracted for by cottonseed oil manufacturers since the war to keep their mills busy during the off season for cottonseed.

Research work by the Bureau of Chemistry at Washington on peanuts has developed a flour which when added in amounts of 20 to 25 per cent to wheat flour produces a bread containing enough protein for normal growth. This offers increased possibilities in the utilization of peanuts in addition to the extraction of peanut oil. Large shipments of copra to this country are also made. Experiments at Washington on copra press cakes indicate that when mixed with corn an adequate protein mixture for cattle feed can be made at reduced cost.

Pulp Wood Swept Out to Sea

High water broke the booms on the North River at Murray, B. C., Canada, and allowed nearly $500,000 of pulp wood belonging to the Cape Breton Pulp & Paper Co. to be swept out to sea. It is estimated that this will probably be a total loss.

Objections to Patent Bill

In an effort to meet objections raised by the industrial chemical industry, Representative Nolan, chairman of the Committee on Patents of the House of Representatives, has not pressed for consideration the bill authorizing the Federal Trade Commission to administer certain inventions and patents. The bill passed the Senate March 22. It also has been reported favorably by the House committee and is now on the House calendar.

It is feared in some quarters that the bill as drawn at present would give undue advantages to both actual and nominal Government inventors. At the request of the chairman of the committee, F. G. Cottrell, the Director of the Bureau of Mines, Carl L. Alsberg, Chief of the Bureau of Chemistry, and A. Stewart, one of the Bureau of Mines' specialists, have undertaken to draft certain restrictive amendments which will meet objections offered by the industrial chemists. Mr. Nolan has declined to reopen the hearings on the bill, which is as follows:

A Bill authorizing the Federal Trade Commission to accept and administer for the benefit of the public and the encouragement of industry, inventions, patents, and patent rights, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Federal Trade Commission be, and hereby is, authorized and empowered to accept assignment of, or license or other rights or powers under, to develop, to issue or refuse to issue licenses under, to encourage the industrial use and application of, and otherwise to administer, on behalf of the United States, under such regulations and in such manner as the President shall prescribe, inventions, patents and patent rights which said commission deems it to the advantage of the public to be so accepted, as these may from time to time be tendered it by employees of the various departments or other establishments of the Government, or by other individuals or agencies; and to co-operate, as necessity may arise, with scientific or other agencies of the Government in the discharge of the duties herein set out.

Sec. 2. That the Federal Trade Commission be, and is hereby, authorized and empowered to collect fees and royalties for licensing said inventions, patents and patent rights in such amounts and in such manner as the President shall direct, and shall deposit the same with the Treasurer of the United States; and of the total amount of such fees and royalties so deposited a certain per centum, to be determined by the President, shall be reserved, set aside, and appropriated as a special fund to be disbursed as directed by the President to remunerate inventors for such of their inventions, patents and patent rights contemplated by this Act as may prove meritorious and of public benefit.

Sec. 3. That the Commissioner of Patents is hereby directed to grant all patents and record all assignments and licenses contemplated by this Act without the payment of any fee.

Canada to Establish a Research Bureau

To meet the keen competition in the industrial world in a more efficient manner, Canada is planning to establish a Bureau of Scientific Research at a cost of $600,000 for the grounds and building and $50,000 for salaries and upkeep. Mr. Cronyn, chairman of the committee appointed to consider this project, visited the bureaus of the United States, and made a report emphasizing the economies effected in public expenses in that country due to the work of the Bureau.

The standardization of all measures used in Canada for length, weight, volume, etc., and all forms of scientific apparatus and units of energy used in industry and public service will be the main work of the Bureau.

Robert W. Hunt the First Hunt Medallist

Herbert Hoover, speaking for the American Institute of Mining and Metallurgical Engineers, accepted a fund for the establishment of the Robert Woolston Hunt medal and award, before a large gathering May 27, 1920, at the Engineering Societies Building, New York City. The fund was proposed by the iron and steel committee of the Institute some months ago, but the privilege of establishing this memorial to the humanism, skill and learning of the Institute's past president was claimed by his partners and employees in business.

The medal is a very striking tablet, containing on one side a likeness of Captain Hunt, and on the other side a brawny steel-worker standing alongside a roll-train. It will be given not oftener than once yearly to the author of the best paper submitted to the Institute on the metallurgy of iron and steel. An award of a sum of money will also be given to the author of a meritorious paper on the same subject, it being understood that younger men only will receive this award, without being thereby debarred from also receiving the medal.

Mr. Hunt's business associate, John J. Cone, and his old friend Charles M. Schwab spoke at length upon his life, achievements and many good works, which are legion. As a fitting climax, President Hoover announced that the iron and steel committee had decided to award the first medal to its namesake, Captain Robert Woolston Hunt, nestor of steel metallurgists.

Belgians Seek Raw Material for Artificial Silk Here

Representatives of Belgian interests in the manufacture of artificial silk are now in this country negotiating for the purchase of cotton linters and chemicals as raw material used in its manufacture. Dr. Emil Bindschedler and his assistant, Dr. Juger, arrived in New York a few days ago to make tests on American linters and chemicals used in the manufacture of artificial silk.

Belgium is fast recovering from the effects of the war and is rapidly building up her industries, among which the production of artificial silk is very important. As no American material has been imported since before the war, she has had to depend upon surplus stock of the Allies. This supply is now running low and with the resumption of the Hungarian and Polish plants in addition to the main plant at Tubize it is necessary to procure larger quantities of raw material.

The Polish plant of Tubize at Tomazo, now a part of the new Polish state, has been enlarged to supply ammunition for the Polish Government in its war against the bolsheviki. Here, in addition to the manufacture of powder, about 9,000 lb. of artificial silk is produced daily, more than 3,000 workers being employed.

Experiment Station Devoted to Non-Metals

One of the new mining experiment stations for which an appropriation probably will be made, according to present plans, it is understood, will be devoted largely to the non-metals. As the non-metals represent the large raw-material supplies for the chemical industries, it is felt that intensive research of the character provided at mining experiment stations should be arranged for.

At present the Bureau of Mines is conducting six mining experiment stations. Four more have been authorized, but no appropriation for their establishment has been made. The sundry civil bill, which is about to become a law, is expected to provide funds for at least two additional stations.

Present Status of Bureau of Standards Samples

The Bureau of Standards will continue to prepare and issue standard samples during the coming fiscal year, although Congress has refused to continue the appropriation for the work. Since the money received from the sales of standard samples has always reverted directly to the Treasury, and is not available to the Bureau for any purpose whatsoever, the cost of procuring, preparing, standardizing and distributing the samples will necessitate the curtailment of other lines of established Bureau activities.

In the light of the above facts, it is earnestly requested that all users of standard samples refrain from any unnecessary waste of the material, and that educational institutions limit their use strictly to primary standardization and to advanced research.

A list of the standard samples issued by the Bureau, together with charges and ordering and shipping regulations, is given in the Bureau of Standards Supplement to Circular No. 25. In the future, standard samples will be issued only to users direct. This policy has been adopted to avoid, as far as possible, any chance of contamination or mixing of samples. Such chemical supply houses as have, in the past, carried a limited supply of certain standard samples for the accommodation of their customers can still render them service by remitting their orders with the proper fees to the Bureau for shipment.

Sample 50, which is a new chrome (3.6 per cent)-tungsten (17.5 per cent)-vanadium (0.75 per cent) steel sample, will be issued on or before July 1. Samples 23a, 0.8C bessemer steel, and 51, a new 1.2C electric furnace steel, will be issued on or before Sept. 1.

Book Reviews

THE PHYSICAL CHEMISTRY OF THE METALS. By *Rudolph Schenck*, translated and annotated by *Reginald S. Dean*. 1st Edition. John Wiley & Sons, Inc., New York, 1919. 239 pp. Price, $3.

This acceptable translation of what ought to become a very widely studied and extremely useful book is very welcome. The German original first appeared in paper covers, and was the verbatim report of a series of lectures delivered at Aix-la-Chapelle before engineers of the Rhenish industrial district to "deepen their understanding" of smelting operations and metallurgical processes. Doubtless the hearer's curiosity was aroused rather than his understanding deepened, for the subject matter covered is so wide that only a broadly educated and studious engineer could grasp all the different phases, while owing to limitation of space only cursory mention could be made of them—evidently a treatment not calculated to "deepen the understanding" of an expert. For instance, in the introductory chapter or Lecture I, on the Properties of Metals, no less than twenty-six sub-topics are considered, many of them worthy of a lecture or a series of lectures in themselves. Fancy compressing into two or three pages such subjects as Polymorphy, Determination of the Transition Point, Enantiotropy and Monotropy, or Electron Theory!

On the other hand, the few words on all these topics cannot but whet the appetite of any seriously-minded student for more and detailed information furnished in the various footnote references to the literature. In the hands of the expert, however, it will contain, in small compass, comprehensive mention of the wide ramifications of physical chemistry as applied to metals, and many side-lights upon any problem he may have under investigation, often with actual data available for use. Thus, Giolitti in his classical studies on cementation of iron and steel was able to use Schenck's Figs. 102, 103 and 104 in arriving at a rational explanation of the bizarre fact that some alloy steels emerged from the case-hardening operation deeply carburized yet superficially oxidized, and to define the precise limits of pressure and temperature in order to avoid such an unwelcome product.

During war times the original book was excessively rare in the United States. Possibly its form was such as not to attract the attention of the general metallurgical profession quickly, and its importations were therefore few in number. At any rate, for several years it was found impossible to purchase a copy or even to secure a loan. Now its appearance in English should do much to "deepen the understanding" by stimulating the study of physical chemistry as applied to smelting, metallurgical working and heat treatment on the part of all those who are really striving to make good metal better. E. E. THUM.

Personal

Dr. C. L. ALSBERG, Chief of the Bureau of Chemistry, has been attending a conference in Chicago at which he met the Bureau's district chiefs and inspectors. The object of the meeting was to plan the work for the next fiscal year.

Dr. J. H. ANDREW, chief of the metallurgical research department of Sir W. G. Armstrong, Whitworth & Co., Manchester, England, has been appointed to the chair of metallurgy in the Royal Technical College, Glasgow, Scotland, vacant by the transfer of Dr. Desch to the University of Sheffield.

E. J. BARTELLS, manager Wood Pipe Export Co., of Portland, Ore., visited San Francisco during the Seventh National Trade Council convention.

J. H. BECQUE has resigned his fellowship at the Mellon Institute to accept the position of assistant superintendent at the Plasterco, Va., plant of the United States Gypsum Co.

C. E. BEECHER, formerly with the Union Oil Co. of California, has been added to the staff of the Bartlesville station of the Bureau of Mines.

M. E. COOLEY, dean of the department of engineering at the University of Michigan, spoke before the Michigan Manufacturers' Association at its annual meeting at Detroit on a plan of the university for helping the country by doing industrial research work for small concerns.

HOWARD ELLIOTT and L. B. STILLWELL were elected directors of the United States Chamber of Commerce at the recent annual meeting at Atlantic City. Mr. Elliott is a member of the American Society of Civil Engineers and chairman of the board of the Northern Pacific R.R. Mr. Stillwell is past president of the American Institute of Consulting Engineers and of the American Society of Electrical Engineers and a member of the American Society of Civil Engineers. Both are from New York City.

Dr. ARTHUR W. DOX has resigned as chief in chemistry of the Iowa Agricultural Experiment Station to accept the position of research chemist for Parke, Davis & Co., Detroit, Mich.

JOHN B. FERGUSON, formerly of the Geophysical Laboratory of the Carnegie Institution of Washington, D. C., and now a member of the research department of the Western Electric Co. of New York City, has accepted a position as associate professor of chemical research at the University of Toronto.

Dr. WILLARD J. FISHER, assistant professor of physics of the University of the Philippines, and since July, 1919, acting head of the department, will leave the university this summer and return to the United States.

L. F. GORDON, business manager of *Ingeniería Internacional*, read the address prepared by James H. McGraw,

president of McGraw-Hill Co., Inc., on "The Service of the Business Press," at the Seventh National Foreign Trade Council convention in San Francisco, Cal.

F. M. KIRSCH, manager Wood Pipe Export Co., delivered an address in San Francisco at the Seventh National Foreign Trade Council convention on "The Webb Law in Operation."

CHARLES F. LEDERER, until recently superintendent of way of the Milwaukee Electric Railway & Light Co., Milwaukee, Wis., has become associated with the rail welding department of the Metal & Thermit Corporation, New York City.

Dr. A. W. OWENS, who has been at the Bureau of Standards as associate chemist in the metallurgical chemistry section for about two years, has resigned and will take up work as research chemist on the staff of the United States Smelting, Refining & Mining Co., about July 1.

D. H. SIMPSON, who has been a member of the physical chemistry section of the Bureau of Standards, leaves this position about June 10 to take up a new line of work in Chicago. This is the third separation from this section within the last few months and it is being considered whether the work of this section will not have to be discontinued until additional funds are available for the chemistry division of the Bureau.

E. T. STANNARD, vice-president of the Alaska Steamship Co., has been elected a vice-president of the Kennecott Copper Corporation. Mr. Stannard will move his headquarters from the mines at Kennecott to Seattle, Wash.

GEORGE H. TOMLINSON has accepted a position as research chemist with the Riordan Pulp & Paper Co., Ltd., at Hawkesbury, Ont.

CHARLES W. TRIGG has changed his headquarters from the Mellon Institute of Industrial Research, where he has been engaged in coffee investigation for the past four years, to the King Coffee Products Corporation of Detroit, Mich., in the capacity of chief chemist. His connection with the former organization will still be retained.

Current Market Reports

The Non-Ferrous Metal Market

New York, May 31, 1920.—Copper market unchanged from spot to July 31. Mercury again weakened, falling from $92 to $87.50. Markets of rare metals, like other markets, very uncertain. Tin declined 2½c. in the last week.

	Cents per Lb.
Copper, electrolytic	19.25
Aluminum, 98 to 99 per cent	32@33

The Chemical and Allied Industrial Markets

New York, May 28, 1920.

General indications seem to point to somewhat less strained conditions than have been prevalent for the past few weeks, although there is little to report in the way of actual business or price changes. The supply of *sodium nitrite* is better than it has been for the past few weeks and offerings as low as 19@19½c. per lb. for car lot and 20@20½c. for less than car lot have been heard during the period. One factor in this item has withdrawn all offerings on the grounds that material sold at this figure would mean a loss when the cost of shipment from abroad is considered. There has been no break as yet in the present *glycerine* rise and although 26½@28½c. per lb. still holds as a firm price, sales as high as 30c. have been rumored during the week. Among the heavy chemicals *carbon tetrachloride* is suffering from lack of transportation facilities and prices ranging from 13½@15½c. per lb. are being asked for spot material which is easily accessible.

COAL-TAR PRODUCTS

The seriousness of the Japanese money situation is making itself felt in this market. Contracts that producers have been striving to get for some time back are being cancelled by foreign buyers, who are finding it impossible, in the present situation, to meet the conditions of their original agreements. The transportation tie-up is not as complete as it was two weeks ago, but nothing in the way of relief to the depleted spot market has arrived. *Naphthalene* is still holding up around 15c. per lb., while flake and balls are difficult to find at 15½@17c. and 16@18c., respectively. Surplus Government supplies of *phenol* are still being offered at 12@20c. per lb., while *benzol* continues in very small offerings with quotations ranging between 27@36c. per gal. for pure, water white, and 25@31c. for the 90 per cent grade.

NAVAL STORES

Turpentine has been gradually declining during the period and latest reports have it as low as $2.27 per gal. There is enough material on the New York market to take care of the local demand, but up to the present there has been no attempt made to resume the exporting of this item. The *rosins* failed to come down with turpentine and as far as can be discovered there is no material being offered, even at the listed prices in the table, which are for the most part wholly nominal.

OILS

The vegetable oil market continues in a weak position with indications of still lower offerings in order to draw the buyers back into the market. Very little interest is being displayed in *linseed,* which came down to $1.65 raw, car lots, and $1.67, boiled, car lots, while *palm,* lagos, also dropped to 12½@13½c. per lb. from 13½@14½c. Offerings of *cocoanut,* ceylon grade, at 17½@18½c. and cochin at 18½@19½c. per lb. seem to be the average prices, which are 1c. below the previous report made last week in this journal.

Chicago, May 26, 1920.

More than one dealer and user of chemicals in Chicago has characterized current conditions as "coming back to earth." Conditions in regard to shipping seem to be improving, in that considerable quantities of all sorts of commodities are being received and bills of lading indicating

goods in transit are coming through the mail with increasing regularity. Shipments from a producing point direct to Chicago are coming through with the least interference while those which are routed through any one of the great freight switching yards are invariably delayed. Receipts here indicate the New York yards as the most congested point, import freight through that terminal being the most difficult of clearance.

Two weeks ago we mentioned that the freight tie-up had served to isolate Chicago and to render quotations here independent of conditions in the rest of the world. This is now true in a slight degree only, as receipts are sufficient to bring this market back into correlation with New York. General inactivity is noted. While this is, in a measure, due to the fact that wise buyers stay out of a market when they know available materials are very scarce, it is felt that general business conditions are mostly to blame. Banking interests everywhere are holding credit lines very tight, and slow deliveries have made purchasers slow in paying bills. This limits the amount of money available. Coupled with this, a well defined feeling of uncertainty as to future industrial and trade conditions renders everyone reluctant to accumulate any great stocks. As a result, users of chemical products are operating on a hand to mouth basis, with an eye on the future.

Heavy Chemicals

Improvement in conditions has made itself felt in an increase in the available supply of *alcohol*. It is not yet plentiful but can now be obtained in reasonable quantities. Today's quotation on *ethyl* grade in barrels is $5.57½ per gal. for immediate delivery. Owing to the high price no one is buying more than enough for immediate needs. Second hands in broken package quantities are bringing $6 to $7 a gal. *Methyl* grade seems harder to get than ethyl. A nominal quotation is made on this grade of $2.65 per gal. for 95 per cent, though none was found offered for actual delivery at that figure. Spot goods could command 10c. higher if the buyer had to have the goods. *Denatured*, 190 proof, while obtainable, continues to increase in price, being offered today at $1.09@$1.11. *Formaldehyde* is about the same as when last mentioned, current small transactions ranging around 62@65c.

Cancellation of large orders of alkali products for the Far East have broken the heavy demand on makers and an immediate reaction in price was felt in *soda ash* and *caustic soda*. The former, quoted a fortnight ago at 4½@5c., is now obtainable at 3¾@4c. on contract. *Caustic soda*, worth 7c. on contract two weeks ago, is from ½c. to ¾c. lower. Spots in both these commodities remain unchanged, as the local stock condition remains bad. Lower prices seem only a matter of a little time, therefore trading is inactive. *Bleaching powder* at 5c. per lb. and *sal soda* at $1.60 cwt., f.o.b. Chicago, show no recent appreciable change.

Under lightened demand, spot quotation on *blue vitriol*, large crystals, is off ½c. from former quotation, to 8c. per lb. Prices of makers for contract delivery show no change. *Copperas* is holding firm at $2.75 cwt., which seems high, but is probably justified by existing scarcity of supply. *Mercury*, closely following the New York market, is offered at $95 a flask, which represents a 10 per cent increase in the past month. *Sodium nitrite* has again been subject to violent fluctuation, today's quotation being around 30c. per lb. The past two weeks have seen quotations on this item ranging from 25c. upward.

Coal-Tar Products

As in other chemical lines, the grip of the traffic tie-up seems to be gradually lessening, though the entire market is, as yet, in bad shape. The entire range of prices seems too high and buyers are necessarily not going beyond positive week-to-week requirements. The market has been spotty for some time, quotations being of value for the one day only. The general trend seems to be downward and must remain so for business to resume a healthy tone. Among the crudes, 28@29c. per gal. is quoted on *benzol*, with producers booked up solid for some time to come and local stocks at the minimum. *Cresol* is in readier supply at 16c. and the trade is absorbing production easily. *Toluol* continues strong at 31c., with producers well sold up. *Naphthalene* remains in heavy demand, but buyers refused to close at recent high figures. Flakes as a result are down 2c. to 15c. a lb. and balls to 16c.

The acids, in general, are strongly held, with but little business being done. *Picric* alone seems in good supply, current price being 24c. per lb. for local stock. *Benzoic* is held at 90c. on U.S.P. grade for later delivery, but scant stocks have run dealers' price up to $1. Technical grade is still quoted at 75c. per lb. Manufacturers are holding firm at 60c. per lb. on *salicylic* acid, c.p. grade, for future delivery. Holders of local stocks have been forced by lack of purchasers to reduce prices to 55c. Fluctuations on all these items are of wide range and rapid. Intermediates remain on too high a level to interest buyers. *Aniline oil*, quoted at 37@38c. per lb., has felt a severe slump in demand, as also has *aniline* salt, quoted at 48@50c. Lower prices must prevail before much business is transacted. A market scarcity has developed in *anthracene*, it now being quoted at $1 per lb. for 80 per cent.

Vegetable Oils

Supply is easier but demand continues light. The general tendency to refrain from buying beyond present-day needs is heavily felt in this line, and although prices have held to quotations last given, except for a few fractional declines, the weakness is evident. Current business in *soya bean*, *corn* and *cottonseed* oils is at a minimum. Some *cocoanut oil* is changing hands on a basis of 17c. per lb. for Manila grade in sellers' tanks, f.o.b. coast. Local quotation on *linseed oil* remains at $2.05 for raw, $2.07 for boiled, in barrels, carload lot quotations on bulk falling off a few cents to $1.60@$1.65. Rail troubles have closed some producers and caused a short supply, but consumption in construction operations has likewise fallen off. The future of this particular item is hard to forecast, though lower prices seem probable.

St. Louis, Mo., May 25, 1920.

The transportation situation, as affected by the rail strike, while continuing to show improvement, is still far from normal. Considerable time must elapse before the present depleted local stocks of chemicals are replenished and conditions become stabilized. Especially is this true for chemicals which are not manufactured locally or where local production is limited. The curtailment of production of other industries which are large consumers of chemicals has to a certain extent relieved the situation.

The demand for heavy chemicals continues to be good and in many cases exceeds the supply.

Sulphuric Acid. — The demand is good and prices show little increase in past two weeks. The 60-deg. grade is quoted at $15 to $16 per ton and the 66-deg. grade $22 per ton. Oleum is quoted at $27.50 per ton.

Muriatic Acid.—The demand continues heavy and local supply is sold up. The 18-deg. grade is quoted at $21 per ton. No increase for past two weeks.

Nitric Acid.—Prices unchanged. Quoted in carload lots at $7 per hundred for 36-deg., $8 for 38-deg., $9 for 40-deg., $10 for 42-deg.

Acetic Acid.—The demand is heavy and local stocks low. Prices show increase. Spot transaction for glacial grade 18½c. per lb.

Phenol.—Demand good and supply plentiful due to local firm disposing of surplus Government stock. Quotation unchanged at 12c. per lb. in large quantities.

Zinc Chloride.—Unchanged and quoted at $2.50 to $2.75 per hundred.

Caustic Soda.—Supply very limited and prices unstable. Quoted at 7c. per lb. for 76-per-cent test in drum.

Sodium Carbonate.—Local supplies very low. Sales reported at $2.25 per hundred.

Soda Ash.—Demand exceeds supply. Quoted carload lots in barrels at $4.50 per hundred.

Sodium Nitrate.—Supply limited and prices increasing. Quotations for spot transactions 6c. per lb.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	.....	$0.65 – $0.75

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	.....	—	$1.25
Alpha naphthol, refined	lb.	.....	—	1.45
Alpha naphthylamine	lb.	.65	—	.70
Aniline oil, drums extra	lb.	.35	—	.40
Aniline salts	lb.	.45	—	.50
Anthracine, 80% in drums (100 lb.)	lb.	.90	—	1.00
Benzaldehyde (f.f.c.)	lb.	2.00	—	2.10
Benzidine, base	lb.	1.35	—	1.40
Benzidine, sulphate	lb.	1.20	—	1.25
Benzoic acid, U.S.P.	lb.	.90	—	1.10
Benzoate of soda, U.S.P.	lb.	.80	—	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27	—	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25	—	.31
Benzyl chloride, 95-97%, refined	lb.	.35	—	.40
Benzyl chloride, tech	lb.	.25	—	.35
Beta naphthol benzoate (nominal)	lb.	.50	—	.65
Beta naphthol, sublimed (nominal)	lb.	.....	—	1.00
Beta naphthol, tech (nominal)	lb.	.75	—	.85
Beta naphthylamine, sublimed	lb.	2.25	—	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18	—	.19
Ortho-cresol, in drums (100 lb.)	lb.	.23	—	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.10	—	1.20
Cresylic acid, 95-97%, dark, in drums	gal.	1.00	—	1.05
Cresylic acid, 50%, first quality, drums	gal.	.65	—	.75
Dichlorbenzol	lb.	.08	—	.10
Diethylaniline	lb.	.....	—	1.80
Dimethylaniline (nominal)	lb.	1.50	—	1.55
Dinitrobenzol	lb.	.30	—	.37
Dinitroclorbenzol	lb.	.30	—	.35
Dinitronaphthaline	lb.	.45	—	.55
Dinitrophenol	lb.	.40	—	.45
Dinitrotoluol	lb.	.40	—	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38	—	.40
Diphenylamine (nominal)	lb.	.....	—	.85
H-acid (nominal)	lb.	2.25	—	2.50
Metaphenylenediamine	lb.	1.15	—	1.30
Monochlorbenzol	lb.	.12	—	.15
Monoethylaniline	lb.	1.70	—	1.85
Naphthaline crushed, in bbls. (250 lb.)	lb.	.15	—	.....
Naphthaline, flake	lb.	.15½	—	.17
Naphthaline, balls	lb.	.16	—	.18
Naphthionic acid, crude	lb.	.75	—	.85
Nitrobenzol	lb.	.14	—	.19
Nitro-naphthaline	lb.	.40	—	.50
Nitro-toluol	lb.	.20	—	.30
Ortho-amidophenol	lb.	3.25	—	4.25
Ortho-dichlor-benzol	lb.	.15	—	.20
Ortho-nitro-phenol	lb.	.80	—	1.25
Ortho-nitro-toluol	lb.	.25	—	.40
Ortho-toluidine	lb.	.35	—	.45
Para-amidophenol, base	lb.	2.50	—	3.50
Para-amidophenol, HCl	lb.	2.50	—	3.25
Para-dichlor-benzol	lb.	.08	—	.12
Paranitraniline	lb.	.....	—	1.65
Para-nitro-toluol	lb.	1.35	—	1.50
Paraphenylenediamine	lb.	2.60	—	3.00
Paratoluidine	lb.	2.00	—	2.50
Phthalic anhydride	lb.	.65	—	.75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12	—	.20
Pyridin	gal.	2.00	—	3.50
Resorcin, technical	lb.	4.25	—	4.50
Resorcin, pure	lb.	6.25	—	6.75

Salicylic acid, tech., in bbls. (110 lb.)	lb.	$0 50 —	$0 52
Salicylic acid, U. S. P.	lb.	55 —	60
Salol	lb.	90 —	1 66
Solvent naphtha, water-white, in drums, 100 gal.	gal.	25 —	34
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	19 —	24
Sulphanilic acid, crude	lb.	.28 —	32
Toluidine	lb.	1 70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	
Toluol, in drums	gal.	.29 —	32
Xylidine, drums, 100 gal.	lb	.44 —	.50
Xylol, pure, in drums	gal	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0 36 —	$0.39
Beeswax, refined, light	lb.	39 —	.40
Beeswax, white pure	lb	.63 —	.68
Carnauba, No. 1, (nominal)	lb.	.93 —	.95
Carnauba, No. 2, regular (nominal)	lb.	.85 —	.88
Carnauba, No. 3, North Country (nominal)	lb.	.44 —	.45
Japan	lb.	.21 —	.22
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09½ —	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	—	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11½ —	.12
Paraffine waxes, refined, 128-130 m.p.	lb.	.13 —	.14
Paraffine waxes, refined, 133-135 m.p.	lb.	.15½ —	.16½
Paraffine waxes, refined, 135-137 m.p.	lb.	.17½ —	.18½
Stearic acid, single pressed	lb.	.25 —	.26
Stearic acid, double pressed	lb.	.26 —	.27
Stearic acid, triple pressed	lb.	.28 —	.29

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.75
Pine oil, pure, dest. dist.	gal.	1.60
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$19 50 —	$20 30
Rosin E-I	280 lb.	20 30 —	20.50
Rosin K-N	280 lb.	21 00 —	23 00
Rosin W. G.-W. W.	280 lb.	23.50 —	24.00
Wood rosin, bbl.	280 lb.	17 80 —	18.50
Spirits of turpentine	gal.	2 27 —	2 30
Wood turpentine, steam dist.	gal.	2 30 —	2.35
Wood turpentine, dest. dist.	gal.	1.90 —	2.00
Pine tar pitch, bbl.	200 lb.	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	15.00
Retort tar, bbl.	500 lb.	15.00 —	15.50
Rosin oil, first run	gal.	.87 —	.89
Rosin oil, second run	gal.	.89 —	.92
Rosin oil, third run	gal.	1.04 —	1.05
Rosin oil, fourth run	gal.	1.12 —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.40
70-72 deg., steel bbls. (85 lb.)	gal.	.38
68-70 deg., steel bbls. (85 lb.)	gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.29

Crude Rubber

Para—Upriver fine	lb.	$0.38 —	$0.38½
Upriver coarse	lb.	28½ —	29½
Upriver caucho ball	lb.	30½ —	
Plantation—First latex crepe	lb.	—	38
Ribbed smoked sheets	lb.	.37½ —	38
Brown crepe, thin, clean	lb.	—	35
Amber crepe No. 1	lb.	—	40

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.18½ —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.22
China wood oil, in bbls.	lb.	.22½ —	.23½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.17 —	.18½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.18½ —	19½
Corn oil, crude, in bbls.	lb.	.17½ —	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.15½ —	.16
Cottonseed oil, summer yellow	lb.	.19 —	19½
Coteonseed oil, winter yellow	lb.	.21 —	.22
Linsed oil, raw, car lots (domestic)	gal.	1.65	
Linseed oil, raw, tank cars (domestic)	gal.	1.60	
Linseed oil, boiled, car lots (domestic)	gal.	1.67	
Olive oil, commercial	gal.	3.10 —	3.25
Palm, Lagos	lb.	.12½ —	13½
Palm, bright red	lb.	.13 —	13½
Palm, Niger	lb.	11 —	12
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.16½ —	17½
Peanut oil, refined, in bbls.	lb.	.22 —	.24
Rapeseed oil, refined in bbls.	gal.	1.70 —	1 72
Rapeseed oil, blown, in bbls.	gal.	1.80 —	1 85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.17 —	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.13 —	13½

FISH

Winter pressed Menhaden	gal.	$1 17 —	$1 18
Yellow bleached Menhaden	gal.	1.20 —	1 22
White bleached Menhaden	gal.	1 23 —	1 24
Blown Menhaden	gal.	1 30 —	1 32

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	$20 00 —	$22 00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	16 00 —	18 00
Barytes, crude, 88% to 94% ba., Kings Creek	net ton	8 00 —	10 00
Blanc fixe, dry	lb.	05½ —	06
Blanc fixe, pulp	ton	60 00 —	80 00
Casein	lb.	15 —	18
Chalk, English, extra light	lb.	07 —	.07
Chalk, English, light	lb.	.05 —	.06
Chalk, English, dense	lb.	04½ —	05
China clay (Kaolin) crude, f.o.b. Pkin, Va	net ton	8 00 —	12 00
China clay (Kaolin), imported, lump	ton	25 00 —	35 00
China clay (Kaolin), imported, powdered	ton	30 00 —	60 00
Feldspar (nominal) f.o.b. N. Y. State	ton	13.50 —	18.00
Feldspar, crude, f.o.b. Maryland and North Carolina, points	net ton	7 50 —	8 00
Feldspar, ground, f.o.b. Baltimore	net ton	18 00 —	25 00
Fire clay, f.o.b. Baltimore	net ton	5 00 —	7 00
Fuller's earth, domestic, powdered	ton	25 00 —	30 00
Fuller's earth, imported, powdered	ton	35.00 —	40 00
Graphite (dust polish grade 30%) Ashland, Ala.	lb	—	0 01
Graphite (dust facing grade 50%) Ashland, Ala.	lb	—	0 01½
Graphite, crucible, 85% carbon Ashland, Ala.	lb.	—	.07
Graphite, crucible, 90% carbon Ashland, Ala.	lb.	—	08½
Pumice stone, imported	lb	03 —	.06
Pumice stone, domestic	lb	02½ —	
Quartz (acid tower) list to head, f.o.b. Baltimore	net ton	—	10 00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore	net ton	—	14 00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton	—	17 00
Shellac, orange, fine nominal	lb	1 50 —	
Shellac, orange, superfine	lb	1 60 —	1 65
Shellac, A. C. garnet	lb	1 30 —	1 35
Soapstone	ton	15 00 —	25 00
Talc, domestic	ton	20 00 —	60 00
Talc, imported	ton	60 00 —	70.00

Refractories

Following prices are f.o.b. Works:

Chrome brick	net ton	$75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	85-90 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250 00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb	.21 —	.22
Ferro-manganese, 70-80% Mn.	gross ton	200 00 —	250 00
Spiegeleisen, 16-20% Mn	gross ton	73 00 —	75 00
Ferro-molybdenum, per lb. of Mo.	lb	2 25 —	2 75
Ferro-silicon, 50%	gross ton	80 00 —	90 00
Ferro-silicon, 75%	gross ton	150 00 —	200 00
Ferro-silicon, 10-15%	gross ton	60 00 —	65 00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb	90 —	1 10
Ferro-uranium, 35-50% of U	lb	7 00 —	
Ferro-vanadium, 30-40% per lb. of contained V	lb	6 50 —	7 75

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3, f.o.b. Atlantic Seaboard	unit	$0 70 —	$0 85
Coke, foundry, f.o.b. ovens	net ton	15 50 —	16 50
Coke, furnace, f.o.b. ovens	net ton	14 50 —	15 50
Petroleum coke, refinery, Atlantic seaboard	net ton	—	24 00
Fluor spar, gravel, f. o. b. mines	net ton	25 00 —	30 00
*Fluor spar, acid grade, lump, f. o. b. Tonuco, Mex.	net ton	30 00 —	45 00
*Fluor spar, acid grade, ground, f.o.b. Tonuco	net ton	55.00 —	65 00
Manganese ore, 45% Mn and over	unit	80 —	85
Manganese ore, chemical (MnO_2)	gross ton	80 00 —	90 00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	75 —	85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7 00 —	10 00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6 50 —	7 50
Uranium oxide, 96%	lb	2 75 —	3 00
Vanadium pentoxide, 99%	lb	12 00 —	14 00
Vanadium Ore	lb.	1 00 —	3 00
Pyrites, foreign, lump	unit	17 —	
Pyrites, foreign, fine	unit	17 —	
Pyrites, domestic, fine	unit	16 —	17½
Ilmenite, 52% TiO_2	lb.	12 —	
Rutile, 95% TiO_2	lb	11 —	
Carnotite, minimum 2% U_3O_8, per lb of U_3O_8	lb.	2 75 —	00
Zircon, washed, iron free	lb.	16 —	..
Monazite, per unit of ThO_2	unit	42 00 —	..

*Nominal

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 14-in.	100 lb	$2 45 —	$4 00
Angles, 3 to 6 in., ¼-in. thick	100 lb	2 45 —	4 00
Tees, 3-in. and larger	100 lb	2 45 —	4 00
Plates	100 lb	4 00	
Rivets, structural, ½-in. and larger	100 lb	4 00	
Rivets, cupheaded for boilers, ½-in. and larger	100 lb	4 50 —	4 50
Sheets, No. 28 black	100 lb	5 50 —	6 00
Sheets, No. 10 blue annealed	100 lb	3 75 —	4 00
Sheets, No. 28 galvanized	100 lb	5 75 —	8 50

For painted corrugated sheets, add 30c. per 100 lb. for 24 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 10c. to 40 cents

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

EL SEGUNDO—The General Chemical Co., 25 Broad St., New York City, has awarded the contract for a group of factory buildings, to the J. G. White Eng. Corp., 43 East Exch. Pl. Estimated cost, $2,000,000.

LOS ANGELES—Wilson & Co., 1000 Lyons St., plans to build an oleomargerine factory. Estimated cost, $100,000.

Colorado

BURLINGTON — The School Bd. plans to build a 2-story, 90x90-ft. high school. A chemical laboratory will be installed in same. Estimated cost, $60,000. H. G. Hoskin, secy.

Connecticut

ELMWOOD (Hartford P. O.)—The Abbot Ball Co. has awarded the contract for the construction of a 1-story, 50x80-ft. factory for the manufacture of steel balls, to the J. H. Grazier Co., 721 Main St., Hartford. Estimated cost, $18,000.

HARTFORD—The Bd. Educ. plans to construct a 2-story, 160x200-ft. high school in the western section of the city. A chemical laboratory will be installed in same. Estimated cost, $500,000. W. Marchant, archt.

MANSFIELD DEPOT—The Mansfield State Training School has awarded the contract for the construction of a 1-story, 40x50-ft. filter plant, etc., to Canning & Leary, Harris Bldg., New London. Estimated cost, $35,000. Noted May 19.

District of Columbia

WASHINGTON—J. A. Wetmore, supervising archt., will receive bids until June 22 for furnishing the labor and materials in connection with the proposed extension to the animal house for the Hygienic Laboratory, United States Public Health Service, here.

Florida

PALATKA—The McGuire Fertilizer Co., Morristown, plans to construct a fertilizer mixing plant in St. John's County near here. Estimated cost, $200,000.

Illinois

AUGUSTA—The Bd. Educ. will soon award the contract for the construction of a 2-story high school here. Laboratory equipment will be installed in same. Estimated cost, $100,000. H. R. Temple, Champaign, archt.

CHICAGO—The Chicago Solder Co., 218 North Union Ave., has awarded the contract for the construction of a 2-story, 50x250-ft. addition to factory, to the E. L. Scheidenhelm Co., 111 West Monroe St. Estimated cost, $100,000. Noted Feb. 4.

Maryland

BALTIMORE — The Maryland Color Printing Co., Holliday and Hillen Sts., has awarded the contract for the construction of a 17-story, 100x110x135-ft. plant, to the Consolidated Eng. Co., 243 Calvert Bldg. Estimated cost, $2,000,000.

CUMBERLAND — The Kelly-Springfield Tire Co., has awarded the contract for the construction of a 3- and 4-story, 575x620-ft. rubber tire plant on River Rd., to the Hunken Conky Constr. Co., Cleveland, Ohio. Estimated cost, $2,000,000.

Minnesota

MINNEAPOLIS—The Modern Fdry. & Machine Co., 4725 Dupont Ave. S., is having plans prepared for the construction of a 1-story, 80x150-ft. steel foundry. Estimated cost, $60,000. L. J. Bedard, pres.

Missouri

ST. LOUIS—The Amer. Bed Co., 1820 McNulty St., has awarded the contract for the construction of a 2-story, 75x130-ft. paint shop on Park Ave., to the Fruin-Colnon Contg. Co., Merchants Laclede Bldg. Estimated cost, $30,000.

New Hampshire

MANCHESTER — The Notre Dame Hospital plans to build a chemical diagnosis building on Concord St. Plans include a surgical, genito-urinary, orthopedic, X-ray, oral surgery, dentistry, and various other departments. Estimated cost, $60,000. G. S. Foster, 967 Elm St., secy.

New Jersey

SAYREVILLE—The borough plans to construct a water supply system which will have a daily capacity of 250,000 gal. Plans include filters, etc. Waldo S. Coulter, 114 Liberty St., New York City, engr.

TRENTON — The Ajax Rubber Co., Breunig Ave., has awarded the contract for the construction of a 4-story, 60x100-ft. rubber factory on North Olden Ave., to the N. A. K. Bugbee Co., 206 East Hanover St. Estimated cost, $60,000.

TRENTON—The Thermoid Rubber Co., Whitehead Rd., has awarded the contract for the construction of a rubber factory addition, to Karno-Smith Co., Broad St. Bank. cost, $175,000. The company is in the market for $100,000 worth of machinery for same.

North Carolina

GASTONIA—The mayor will receive bids until June 8 for the construction of a waterworks extension and sewer system including a 2,000,000-gal. filtration tank and a purification plant. W. M. Piatt, Durham, engr.

Ohio

AKRON—The Supreme Cord Tire & Rubber Co. plans to construct a factory on a 9½-acre site on Home Ave.

CLEVELAND—The Cleveland Welding & Mfg. Co., West 117th St. and Berea Rd., will soon award the contract for the construction of a 1-story, 90x155-ft. factory. Estimated cost, $75,000.

CLEVELAND—The Modern Aluminum Fdry. Co., 4613 Payne Ave., has awarded the contract for the construction of a 1-story, 50x143-ft. factory addition, to H. G. Claxton, Vickers Bldg. Estimated cost, $50,000.

CUYAHOGA FALLS—The Falls Rubber Co. has awarded the contract for the construction of a 3-story, 61x84-ft. factory addition, to the A. A. Lane Constr. Co., 1836 Euclid Ave., Cleveland. Estimated cost, $60,000. Noted May 4.

Pennsylvania

PHILADELPHIA—The Yarnall Paint Co., 1026 Race St., has awarded the contract for altering a paint factory, to R. C. Ballinger & Co., 218 North 13th St. Estimated cost, $30,000.

West Virginia

BARRACKSVILLE—The Bd. Educ. plans to build a high school. A chemical and physical laboratory will be installed in same. L. L. Friend, state supervisor of high school buildings.

BLUEFIELD—The Bd. Educ. plans to build a junior high school. A chemical and physical laboratory will be installed in same. Total estimated cost, $200,000. L. L. Friend, state supervisor of high school buildings.

FAIRMONT — The Union Independent School Bd. plans to build a high school in the eastern section of the city. A chemical and physical laboratory will be installed in same. Estimated cost, $125,000. L. L. Friend, state supervisor of high school buildings.

HUNTINGTON—The Bd. Educ. plans to build a junior high school. A chemical and physical laboratory will be installed in same. A $62,000 bond issue has been passed for the project. L. L. Friend, state supervisor of high school buildings.

MONTGOMERY—The Bd. Educ. plans to build a high school. A chemical and physical laboratory will be installed in same. Estimated cost, $125,000. L. L. Friend, state supervisor of high school buildings.

RAVENSWOOD—The Bd. Educ. plans to build a high school. A chemical and physical laboratory will be installed in same. A $62,000 bond issue has been passed for the project. L. L. Friend, state supervisor of high school buildings.

Ontario

CHATHAM—The city plans to install 3 mechanical pressure filters in connection with its waterworks system. Estimated cost, $30,000. F. Adams, City Hall, engr.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold a regular meeting June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its twelfth semi-annual meeting as follows: June 28 and 29 will be spent in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE CANADIAN INDUSTRIAL CONGRESS will be held at Victoria, B. C., June 2 to 10.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City. Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NEW JERSEY CHEMICAL SOCIETY will hold a regular meeting and ladies' day Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J.

THE NORTHERN OHIO SECTION OF THE AMERICAN CERAMIC SOCIETY will hold its summer meeting June 7 at Sandusky, Ohio. Visits will be made to the Sandusky Bulb Works of the General Electric Co., and the business meetings will be held at Cedar Point.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

The Federated American Engineering Societies

SELDOM does the habitué of technical and general gatherings absorb so many inspirational thoughts tumbling fast through a medium electrified with a sharp clash of intense purpose as at Washington last week. This alone would mark the recent organization of The Federated American Engineering Societies. Not only were the brief and pithy addresses from eminent engineers in various walks of life full of allusion to the widespread value of engineering thought and achievements, but even the sharpest discussion was based entirely upon the best and most effective method of giving service. Service was the keynote—not struck by the first speaker of the meeting and then forgotten, but animating the proceedings to the end.

As already noted in these columns, very divergent views may readily be held by any two men as to the proper way to effect a national organization through which the engineer collectively may exert the influence his technical training and moral integrity deserve. (It is perhaps unnecessary to argue that at no recent instant has the need for unselfish and competent service to the public been so pressing.) Unsatisfied with the apparent conservatism of the old-established national and regional engineering societies, the American Association of Engineers has gathered together in a democratic organization many thousand men—from engineers of highest technical achievement to neophites—and has already executed difficult and salutary undertakings most creditably. Leavened by this yeast, or in the natural course of events—it does not matter—even the most conservative of the older organizations recognized the insistent desire on the part of an engineer to become an influential citizen, and actively sponsored the idea of federating themselves together to promote this consummation.

At the organizing conference there was consequently much inflammable material. It was only natural to doubt whether the democratic idea was so fundamentally divergent from the federation idea that the societies embracing these tenets could find no common ground. Those who could not measure the bigness of the individual delegates freely predicted steam roller methods on the part of the founder societies and their satellites, and last-ditch obstruction from the A.A.E. and its sympathizers. However, the event confirmed the optimistic. The activity of an impromptu steering committee was instantly halted by the absolute impartiality of CALVERT TOWNLEY, the permanent chairman, and the bitterness which is inseparable in a losing fight never even approached the petty devices it so often encourages.

This happy condition was possible only because it was the instinctive desire of the hundred or more individuals present to organize nationally for service—service to the public and the engineering profession. This was the evident common ground. Debate as to the most nearly perfect method of reaching this end never descended to the acrimonious, and often approached the inspiring. Particularly it was evident at the climax of the meeting, when on the first roll call taken on the resolution "that it is the sense of this convention that the proposed organization should be an organization of societies or affiliations and not of individuals," the A.A.E. representatives, responding first, voted yes to a motion which the casual observer might think would submerge their individuality, simply stating that they were present not as obstructionists, but as co-operators, to aid in the work in any way possible.

This, it seems apparent, should be the principal thought carried home by the various delegates. Many provisions of the proposed constitution and bylaws may not appeal strongly to individual societies or individual members of the societies. The whole plan of operations may appear fundamentally wrong. Frankly, we may confess that we are yet to be convinced that a federation is better than a democracy, for reasons some of which have already been given in these columns. But every one, it seems certain, should approach the debatable points from the standpoint so clearly seen at Washington, that the common ground is service, and that engineers should co-operate and not obstruct. The least each individual can do is to consider carefully the debatable features from the standpoint that the general movement is desirable. If any detail is wrong, co-operate in a sincere effort to correct it! Help as far as you can! The least which that involves is a sincere hope that any finally accepted organization may succeed, and will not need to overcome active enmity.

Make It Definite

THE work of the American Chemical Society Committee on Standardized Apparatus has led the chairman to make a very excellent suggestion which the authors of technical articles should heed. He recommends that the description and illustration of apparatus should be made as definite as possible, particularly including the complete dimensions. Anyone who has undertaken to reproduce the results of physical measurements or organic reactions in the laboratory as described by other investigators knows how frequently he is at a loss to know just how some essential detail of the apparatus was cared for. All too much of our scientific literature is seriously lacking in definiteness and every author who wishes to make his record of investigation of greatest value to posterity should bear in mind the need of giving all essential dimensions of apparatus very clearly.

The Haber Process In the United States

WHILE it is conceded that the Haber process of nitrogen fixation is still in the experimental stage in this country, as evidenced by the fact that continuous production on any considerable scale has not been accomplished, much progress has been made toward its ultimate commercial development. Within the next few years we should witness the successful completion of experimental work on catalysts by the Army Ordnance and the General Chemical Co.; the reconstruction of U. S. N. P. No. 1 at Sheffield, Ala., and the completion of the plant of the Atmospheric Nitrogen Corporation at Syracuse, N. Y. When these two small plants are producing ammonia without interruption the demonstration of the American adaptation of the method will have been successfully made.

We are surfeited these days with the output of the professional muckrakers who make the mistake of attacking legitimate governmental activities along with the projects, very few in number, which really deserve investigation. The large enterprises started during the war and temporarily abandoned because we were blessed with an earlier suspension of hostilities than was expected are still as important to the nation as if the fighting had continued. The efforts expended will be just as valuable in the prosecution or, let us hope, prevention of the next war. For the person who believes that wars may be ended for all time is neither a student of history nor of human nature as manifested collectively by national existence.

It is further very fortunate that the nitrogen industry may serve the interests of peace while keeping pace with the progress of other nations in the art of war. It excels the Army and Navy in this regard and is quite as essential for national preparedness.

Let not the efforts of those technical men who would have preferred to be heroes in actual combat be in vain! They labored sleeplessly in the hope of supporting the men at the front and when the Armistice was signed said, "Well, anyway, we've done a devil of a lot for the next time!"

The nitrogen fixation business must be carried on by the Government first as a measure of preparedness and second to meet the needs of the fertilizer industry. The question of wasteful expenditures or graft in the building of the plants is a matter for prosecution in the courts and has nothing to do with proposed operation and development by the Government of a scientific process for manufacturing a commodity that can be turned to the uses of war or peace.

The Compleat Letter Writer

WHEN the Extraordinary Grand Jury of the County of New York was investigating the curious charge made by Mayor HYLAN that the officers of the subway had conspired with their employees to induce them to strike last August, it was discovered that the Mayor's appeal to the striking men to put no faith in their employers but rather to rally round him was written in a certain familiar yellow-newspaper style. Persistent investigation brought out the fact that the manifesto was prepared for him by the city editor of WILLIAM RANDOLPH HEARST'S notorious New York *American*.

When Captain VON PAPEN of unpleasant memory left Nazareth in Palestine in great haste, owing to the advent of the British forces there, he left behind him a case known in naval parlance as a ditty box, which contained his papers. Among these were letters from his erstwhile companion in the United States, Kapitan zur See BOY-ED. In one of these BOY-ED recalled his manifesto to the American people which he issued on his enforced departure from these shores, and which reflected, to put it mildly, what he considered the unfairness of the public in regard to his precious activities—more particularly with firebugs and dynamiters. Most of our readers will recall a feeling of warmth about the neck on reading it. In a letter found in the box he explained to VON PAPEN, according to *The English Review*, that he had had the aid of SAMUEL UNTERMYER of the New York Bar in preparing the precious document.

Now we have no idea what meditations take place in Mayor HYLAN'S mind, because nearly three years' experience as citizens under his rule have proved this to be impossible. But in turning the matter over to the bureau of his friend HEARST he issued what was no less than an incitement to riot. And whatever excuse Captain BOY-ED may have thought to warrant him in his efforts at destruction, his expression resulted in one of the most remarkable and impertinent harangues ever offered to a justly offended people. And although in each case it was dirty work, it cannot be denied that both HEARST and UNTERMYER are men of unusual attainments and signal ability.

The point we want to bring out by these two examples of vicarious fulmination is that if one does not know what to say, it is better not to get somebody else to say anything. It pays to advertise, because the advertiser is sure to have an idea, and he is abundantly warranted in getting help to give his idea competent expression. But if he has only a grouch and is so angry as to be incoherent, there isn't any kind of ability that can translate his anger into reasonableness. The best HEARST'S man could do was to preach his employer's gospel of riot, and the best even SAMUEL UNTERMYER could do was to scold.

Honorary Degrees In Chemistry

HONORARY degrees are very pleasant to receive, and once in a while a chemist gets one. The occasions are, however, rather rare. The University of Pittsburgh nearly every year confers the degree of Doctor of Chemistry upon some man of great achievement and distinction, but this, we believe, is the only institution in the United States that confers the degree at all. Otherwise such chemists as answer to the appellation "Doctor" without a disturbing twinge are usually Doctors of Philosophy, for which they have labored long, either here or abroad. Most German chemists also seem to be Doctors of Philosophy, and time was when, at all events at some universities, an "inaugural dissertation" on almost any subject was enough to pass them, while the oral examination was but little more than a formality. In other universities such doctorates required as much work as they do here. But the *mores* are different. Our technical schools, unless associated with a university, do not confer doctorates, and the great majority of chemists do not take them. Many of the

leaders in chemical thought in this country are undoctored. It has been proposed lately that certain colleges and universities could do a considerable service by setting aside, as it were, three honorary doctorates in science to be awarded to men resident in that state in which the institution is located, who have contributed important and distinguished work in chemistry or physics. This would require the appointment of a high commission consisting of three or four men of exalted standing in science who would recommend to the trustees the names of men entitled to such distinction. It would require, of course, that the trustees work in harmony with the commission appointed by them, and that politics be avoided. As soon as politics get into the thing the whole plan would be ruined. There is no Republican or Democratic science. But granted the proper appointment of such a commission, there is no reason why the plan should not work very well.

In the first place, it would add to the alumni of the conferring institution a body of men of science who, by their works, would do honor to it. Such alumni, being neighbors, would be disposed to contribute lectures and talks on scientific subjects to the inspiration of its students. It is fair to assume that such a commission would see to it that its candidates be men of worth in other respects, in addition to their achievements in science; but their scientific achievements would have to be genuine. It would bring the progress of chemistry and physics into the public eye and explain to the world why achievement in science is worthy of honor.

The title of Doctor, like that of Professor, has a variable application. In France a dancing master is a professor and here a chiropodist usually has the courtesy title of "Doc," but these are not official. There is a pleasant dignity to the title of Doctor of Science, as there is to that of Laws, and the plan to confer a limited number of these, *honoris causa*, to men who have achieved merit sounds reasonable to us.

Steel Prices And Other Prices

THE steel industry has long distinguished itself for exhibiting kaleidoscopic changes. Now it outdoes itself in one respect. It eliminates time entirely and exhibits different phases at the same instant. "Declines in commodity prices" are being discussed by almost everyone, with all sorts of opinions expressed. A very reasonable opinion is that in the readjustment now occurring in the markets it is not chiefly a case of a horizontal reduction all along the line, but rather of readjustment, through improper alignments in prices having arisen. The net result of the whole thing may be a decline in the average of all prices, but the most pronounced changes will be in relations. One commodity may advance in relation to another commodity by remaining stationary while the other declines, or by declining less than the other.

Behold what the steel industry presents! One asks which commodities will remain stationary and which will decline. Does steel belong to the one class or the other? It does both. For months it has presented several different markets. There are a few men in the iron and steel business who have lived a longer business life than has the steel market, for excepting the part played by the bessemer rail many years ago steel as the dominant factor in the market for wrought ferrous products is only between twenty-five and thirty years old. One of the old-timers, whose experience covered years of the old wrought iron or puddled iron market, remarks that never before had he seen the spectacle of there being more than one distinct market.

There is the Steel Corporation market, the Steel Corporation adhering rigidly to the Industrial Board schedule of prices which became effective March 21, 1919. On bars, shapes and plates the prices are respectively 2.35c., 2.45c. and 2.65c. Then there is the market of certain large independents, for delivery in say from two to five months, the prices being approximately 3c., 3.10c. and 3.25c. Finally, there has been a prompt or spot shipment market at prices much higher still, both bars and shapes having sold at 4.50c. in mill lots.

For some time the question was whether Mahomet would go to the mountain or the reverse. Should the prompt market continue, the Steel Corporation would have to advance its prices or become hopelessly oversold, thus extinguishing itself as a market factor. Otherwise the prompt market would have to drop to a lower level.

Considering the great increase in the volume of money and credit since before the war, high wage rates and high costs everywhere, there can be no such thing as an early return, if there ever can be a return, to prewar levels. One may conclude that some prices are not too high and that other prices are altogether too high. Illustrations can be found. For instance, comparisons of certain descriptions of hardware and tools, made from substantially the same raw materials and by substantially the same classes of workmen, show that some articles have advanced much more than others, when the change in cost of production must have been substantially the same.

If the highest prices are to come down and the lowest prices are to remain as they have been, this interesting steel industry is prepared. It has had three markets, all ready provided. The laws of economics, of supply and demand, of sentiment or whatever it may be that is to make the markets that are to come out of the present readjustment can take their choice of these steel markets, picking out the one that suits the conditions under which American business is to go ahead for the long pull.

The Industrial Board steel prices are about 80 per cent above the ten-year pre-war average of steel prices. That is quite moderate, considering that Bradstreet's last index number, for May 1, was 139 per cent above its ten-year pre-war average. Some steel, however, has sold within the past few months at about double the Industrial Board schedule, which would make it 160 per cent above the pre-war average, and that is obviously too high.

Pig iron, however, has made a market for itself, and it presents only one market. There is no notable delivery premium. While there is little if any business being done for far forward deliveries, the furnaces would not quote materially different prices from those lately ruling for early deliveries. Pig iron now stands between the low steel market and the high steel market. One would lose money buying pig iron at present prices and converting it into steel to be sold at Industrial Board prices, while he would make a great deal of money by selling at the highest steel market. Not having a collection of markets to select from, pig iron may have to make a new market to conform to whatever market the steel situation crystallizes into.

Readers' Views and Comments

Prolongation of German Patents and Useful Models

To the Editor of Chemical & Metallurgical Engineering

SIR:—Enclosed you will find an abstract of a letter from one of my German associates in regard to the prolongation of German patents and useful models. It may be of interest to your subscribers to know as soon as possible of the advantages offered by the new law.

A law has been passed rather abruptly by the German Nationalversammlung allowing the prolongation for five years of patents and useful models suffering from the war. Pending patent applications probably included.

Prolongation only on special motion to the patent office.

Term for filing the motion two months for patents and models already lapsed; six months for all other patents and models, beginning with May 14, 1920.

Motion to show the facts why the patent could not be exploited adequately during the war and prima facie evidence only to prove these facts.

No difference is made between German and foreign patentees.

Procedure before the patent office secret, no opposition from interested parties.

Rules for the execution of the law not yet issued.

The law is of a very liberal spirit, so that all patentees of German patents who were handicapped by the war should make use of it.

As to the lapsed patents, it is necessary to have the instructions to file motions at once, as an overcrowding of all patent attorneys' offices is sure to come very soon.

OTTO K. ZWINGENBERGER.

New York City.

A Rapid Method for the Determination of Tin in Brass and Bronze

To the Editor of Chemical & Metallurgical Engineering

SIR:—The following method was worked out by the writer in an attempt to avoid the troublesome process of purifying the precipitate of metastannic acid by fusion with sodium carbonate and sulphur. The method is simply a modification of the well-known method for the determination of tin in ores. It has proven quite as accurate and much less troublesome than any of the gravimetric methods the writer has used.

Weigh out 0.5 to 5.0 g. of the sample (according to the amount of tin present) into a 250-c.c. beaker and dissolve in 10 to 25 c.c. of aqua regia. Dilute with water, heat to boiling and precipitate the tin with a slight excess of ammonium hydroxide. Filter off the precipitate of stannic acid and wash with hot water. Place a 500-c.c. Erlenmeyer flask under the funnel and dissolve the precipitate on the filter with hot (1 : 1) hydrochloric acid, washing the filter thoroughly with hot water. To the filtrate in the flask, add enough conc. hydrochloric acid to bring the total acid present in the solution up to 100 c.c. Dilute to 300 to 350 c.c., place a coil of pure nickel in the flask and boil for one hour, the flask being covered with a small watch glass. At the end of this time, remove from the hot-plate, drop in a small lump of marble or calcite and cool to room temperature or cooler. Remove the nickel coil, washing the adhering solution back into the flask, add a few c.c. of starch solution and titrate to a blue color with standard iodine solution.

The standard iodine solution is prepared by dissolving 11 g. of pure, resublimed iodine and 20 g. of potassium iodide in a little water and diluting to one liter. One c.c. of this solution is equivalent to approximately 0.005 g. of tin. The exact value of the solution is best determined by titrating a solution of pure tin.

As stannous chloride is quite readily oxdized, it is very important that the flask be kept full of CO_2 after removing from the source of heat in order to exclude the air. This end is quite satisfactorily accomplished by the use of marble or calcite, of which about 1 c.c. is usually sufficient. It should be completely dissolved when the solution is titrated. The writer has found that if care is exercised, the elaborate CO_2 generating apparatus described by some authors is entirely unnecessary for technical work. The operator should determine the amount of iodine necessary to give an end point with a solution containing no tin and should deduct this blank from each burette reading.

The nickel coil is made by cutting a strip about 1 in. wide from a sheet of pure nickel foil about $\frac{1}{32}$ thick and rolling it into a coil small enough to pass easily through the mouth of the flask. This coil is removed from the solution by means of a nickel wire about 6 in. in length and having about $\frac{1}{4}$ in. of one end bent at right angles. The other end may be fused into a length of glass tubing which serves as a handle.

The titration should be performed as rapidly as possible to avoid oxidation by the air. There are no interferences when the solution is cooled below 40 deg. C., though the copper, if left in the solution, obscures the end point.

The acid strength of the solution should be at least 25 per cent by volume. L. R. RAYMOND.

Flat River, Mo.

Industrial Alcohol Regulations

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am pleased to forward you the following changes which have been made in the formulas for specially denatured alcohol, since the publication of my article on them in your issue of March 17, vol. 22, No. 11, pp. 513-518.

Formula 25 has been changed so that it is now composed of 100 gal. of ethyl alcohol, 20 lb. iodine and 15 lb. potassium iodide.

Formula 34 has been authorized, which consists of 100 gal. of ethyl alcohol and 5 gal. of tetrachlorethane. This formula is authorized for use in the manufacture of artificial silk.

Formula 35 has been authorized, which consists of 100 gal. of ethyl alcohol and 35 gal. of ethyl acetate. This formula has been authorized for use in the manufacture of acetparamidophenolsalol.

These formulas, you understand, are specially denatured alcohol and are subject to supervision as to distribution and use by the U. S. Internal Revenue Bureau.

B. R. TUNISON.

U. S. Industrial Alcohol Co.
New York City.

Separation of Fixed Oils From Soap-Water Emulsions

A Study of the Phenomena Exhibited by Emulsions of Oils in Aqueous Soap Solutions—Classification of Emulsions—Effects of Dilution, Salting and Various Physical Forces and Their Possible Application in Oil-Recovery Processes

By EUGENE E. AYRES, JR.

THE following discussion of emulsions of oils and soap-waters is not based upon any purposed and consecutive research, nor is any reference made to the rather copious literature. Each year the writer comes in contact with hundreds of men, each keenly intent upon some emulsion problem. To ninety-nine out of each hundred the science of colloids and of physical chemistry is exceedingly vague, and yet these men are often successful in solving their problems. They work in the dark, and they are to that extent handicapped, but often the freshest ideas come from those whose points of view are naïve. The following discussion is an attempt to analyze and interpret the collective observations of these "practical investigators."

It is convenient at the outset to make several reservations. Only the types of emulsions encountered in industrial manufacture are included in this discussion. Naturally, it has not been attempted to completely cover the types of practical importance. Zinc and lime soaps, for example, or rosin soaps, or the "soaps," so called, derived by neutralization of organic acids in petroleum, or the soaps of volatile fatty acids—none of these cases is discussed. By "soap" is meant the caustic alkali soaps of the common higher fatty acids. Similarly, the sulphonated fatty compounds and the amides of fatty compounds have been ignored.

Classification of Emulsions

Simple emulsions of oil and water may be classified as

1. Those in which water is suspended in oil, and
2. Those in which oil is suspended in water.

Many industrial emulsions are not "simple," but may be technically classed as "complex." A complex emulsion is one in which the dispersed liquid does not consist merely of globules of oil or of water, but in which the suspended globules are themselves emulsions with tiny globules of liquid suspended in them.

Some emulsions are much more complicated in structure than this, especially when suspended particles are ultra-microscopic, but our definition of "complex" emulsions has the advantage of serving our purpose without confusing the issue.

We may make a complex emulsion of the mutually insoluble liquids A and B. The bulk of the mixture is A. The globules suspended in A consist primarily of B, but still smaller globules of A are suspended in each globule of B. A concrete illustration is found in the emulsion obtained when a saponifiable oil is warmed and agitated with a solution of caustic soda sufficient in amount to saponify only a small proportion of the oil. The oil is the A liquid, and the aqueous soap solution is the B liquid. An example of the opposite type is formed when crude petroleum is thoroughly agitated with two or more volumes of water. Here water is the A liquid, while oil is the B liquid.

A "saturated" emulsion is one in which the globules are packed together as tightly as possible in the space provided by the continuous liquid. If small spheres of uniform size are crowded into a given space, the volume taken up by the spheres will be a definite percentage of the volume of the given space. This percentage is independent of the size of the spheres. But if, in such a system, we should insert smaller spheres in the spaces still available, the percentage will be higher. Mathematically speaking, the function is a variable which approaches but can never reach a limit of 100 per cent. The emulsions met with in practice always contain globules of various size—some larger, and some smaller than average. But industrial emulsions rarely contain more than 50 per cent of the dispersed phase. The writer has never seen an industrial emulsion containing more than 80 per cent of the dispersed phase.

A "dilute" emulsion is obviously one that contains only a small percentage of dispersed liquid. To "concentrate" an emulsion is to separate from a dilute emulsion as much of the continuous liquid as possible, leaving a saturated emulsion.

Concentration of dilute emulsions is practiced commonly in many industries.

Simple and Complex Oil-Soap-Water Emulsions

While the definitions suggested above are still fresh in mind, consider the soap-water emulsion as a type. If the emulsion is simple, the aqueous soap solution is the continuous liquid with the oil suspended as globules. If the emulsion is complex, the oil is continuous with suspended globules of simple emulsion wherein water is continuous. The writer has seen no exceptions to this rule. If we were to take, for example, a liter of oil and agitate with one c.c. of soap solution, the emulsion would be invariably complex. As the oil is present in such large proportion, the oil is obviously continuous. If the suspended soap-water is separated (say by gravity settling), it will be found that oil globules are suspended in the soap-water unless gravity has also separated the simple emulsion. There are few cases where soap-water can be completely freed from suspended oil globules by subsidence (gravity or centrifugal), while it is a general rule that the continuous oil of a complex emulsion can be freed with relative ease from the suspended emulsions by subsidence.

Take the converse example of one liter of soap-water with one c.c. of oil. This emulsion will always be a simple emulsion.

If an emulsion of oil and soap-water contains more than 80 per cent oil, it is reasonably safe to conclude that the emulsion is complex. If the oil content is below 20 per cent, the emulsion must be simple. The range between 20 and 80 per cent may belong to either

class, but in nearly every case up to 50 per cent it will be found that the emulsion is simple.

Without recourse to microscopic examination it is easy enough to determine whether oil or water is continuous in an emulsion. If the emulsion is miscible with water, water must be the continuous phase of the emulsion. If oil is continuous, the emulsion will be miscible with oil. Of course, there are cases of true emulsoids where we find miscibility with both oil and water, but this discussion has nothing to do with such cases. The true emulsoid must be ruled out forthwith.

For industrial emulsions, a convenient test is to pour a few drops of the emulsion into a beaker of water. If the emulsion diffuses through the water, water must be continuous in the emulsion. In the case of a soap-water emulsion, the investigator may draw one other inference—the emulsion is simple, with suspended globules of oil. If the emulsion does not diffuse through the water, oil is continuous, and in the case of soap-water emulsions, the emulsion is complex with suspended globules of simple emulsion.

Super-Saturated Emulsions

There are what may be termed "super-saturated" emulsions, which may be described as imperfect mixtures of oil with a simple saturated emulsion. The excess oil is not present in sufficient amount to form a primary continuous phase, and this oil is not globular. Such a mixture is possible only when the emulsion is of high viscosity, for otherwise this excess oil would immediately separate. In the diffusion test, the presence of such oil is indicated by a diffusion of the emulsion proper while the excess oil remains on the surface of the water.

Super-saturated emulsions are very common in the industries, but inasmuch as the recovery of the excess oil is so simple a matter, no reference to super-saturated emulsions will be hereafter made.

Persistence of Emulsions

The continuous oil may be most easily separated from a complex soap-water emulsion when the aqueous phase contains a high concentration of soap. For this reason, when a rancid vegetable oil is refined with caustic soda, it is desirable to employ a caustic soda solution of high strength. Weak caustic soda solutions tend to give complex emulsions in which it is difficult to produce a "break," with subsequent settling of simple emulsion. The strength of caustic soda solution is limited only by refining conditions that have nothing to do with emulsion stability.

Simple soap-water emulsions may contain oil globules of two sorts:

(1) Globules that are "fixed"—that will remain intact as globules until something happens—chemical or physical—to unite them, and

(2) Globules that are temporary—that have been formed by agitation, precipitation or what not, and that will unite to form larger globules that yield readily to subsidence.

The only requirement for the agglomeration of these "temporary" globules from the soap-water is sufficient elapsed time. To agglomerate the "fixed" globules without chemically changing the character of the soap-water is an extremely difficult matter. The writer knows of no instance where such agglomeration is accomplished on a large scale. It is common practice to allow an emulsion to stand in a tank or to pass through a high-speed centrifugal to skim off the oil that can be so separated. But some oil is left behind, and additional subsidence fails to separate it.

Character of Oil and Soap Solution Important

What governs the percentage of oil removable and of oil fixed? The biggest factor is the character of the oil. In general a glyceride of a fatty acid has a much higher "fixed concentration" than a liquid hydrocarbon. It is possible to incorporate permanently more olive oil than lubricating oil with any given soap solution. But there are some miscellaneous oils and greases and waxes of vegetable or animal origin that give a higher fixed concentration than the fatty acid vegetable and animal oils and fats. Examples may be found in certain constituents of wool grease and in the organic "impurities" in crude vegetable oils. The fixed concentration of any commercial oil as a whole is much the same as the fixed concentration of its worst component. For instance, a little linseed oil dissolved in kerosene will raise the percentage of permanently emulsified impure kerosene almost to the value of linseed oil itself. The trace of organic impurity in crude cottonseed oil makes the latter an easily emulsified oil.

In many cases the fixed concentration is coincident with the saturation point. This is not true of any pure glyceride and even less of any pure hydrocarbon.

Next in importance among the factors involved in fixed concentration is the character of the soap solution. This involves soap concentration, the kind of soap, alkalinity, electrolytes and protective colloids. The lower the soap concentration and the alkalinity, the lower the percentage of permanently emulsified oil. The effect of alkalinity on emulsions of easily saponifiable oils may not be readily noted because of saponification reactions. The effect of electrolytes is erratic and will be discussed later. Soluble electrolytes are of course limited to salts of metals of unit valence because of the insolubility in water of soaps of metals of higher valence. Little difference has been noted between various pure soaps, but commercial soaps differ because of the effect of non-fatty-acid impurities. A trace of a water-insoluble soap (zinc or calcium) may or may not increase the fixed concentration.

The fixed concentration is not greatly influenced by temperature.

Stable Emulsions

When all "temporarily emulsified" oil has been permitted to agglomerate and separate, the residual soap-water emulsion at its fixed concentration of dispersed oil is regarded as a stable emulsion. The stability is of two kinds:

(1) A resistance to agglomeration, or the merging of globules (with accompanying subsidence) to form a continuous oil phase; and

(2) A resistance to a concentration of the emulsion, or the subsidence of globules intact to produce on the one hand a saturated emulsion, and, on the other hand, soap-water with appreciably less oil in suspension.

The stability of emulsions is regarded as a phenomenon of surface tension, and reactions that affect surface tension will likewise affect stability. But it is an odd fact that reactions which diminish the tendency for globules to maintain their uniform distribution throughout the soap-water medium will usually increase their resistance toward agglomeration. The conspicuous example of this interesting effect is found in

soap-water emulsions of increased alkalinity. The higher the alkalinity (caustic soda or normal sodium carbonate, for instance), the less likely we are to succeed in breaking down the globular formation to obtain continuous oil, but the more likely we are to concentrate the globules intact to form a saturated emulsion. Generally speaking, it is much more difficult to agglomerate in a soap-water emulsion than it is to cause a separation by subsidence of globules. It is believed that this is a highly important item to keep in mind. Chemists have been too often accustomed to measure the success of an expedient for separation by the yield of free oil without taking into account the changes that may have taken place in concentration. This naturally arises from the fact that oil is easily recognized from appearance, while emulsions more or less concentrated look much the same. As a case in point, we may quote the following procedure:

A certain soap-water emulsion contained 10 per cent of oil at its fixed concentration. On standing for ten hours, samples of the emulsion from the surface and from the bottom analyzed a uniform oil percentage (because the viscosity was too high for appreciable gravity subsidence in the allotted time). One per cent of caustic soda was added. After standing one hour, no free oil had appeared, but the liquid at the bottom was relatively clear, while the supernatant liquid was thick and opaque. The clear soap-water was drawn off and tested. It contained less than 0.5 per cent oil. The concentrated emulsion was mixed with a quantity of 1 per cent aqueous solution of caustic soda equal to the soap solution withdrawn, and settled again for one hour. No free oil appeared, but a subsidence of globules again took place. After a third similar treatment, the concentration of emulsifying agents had been reduced to such a low point by the successive dilutions that the globules agglomerated and a fairly complete yield of continuous oil was obtained.

Needless to say, such a procedure is impractical for saponifiable oils because of losses of oils by saponification. But though, for this reason, yields are necessarily low, separation is almost as effective as with unsaponifiable oils, in spite of the maintenance of a relatively unform soap concentration (by saponification). This is because a high fixed concentration is not possible with pure glycerides and soaps, and involves the presence of impurities.

In the commercial soap-water emulsion, the most common emulsifying agent is material that, although unsaponifiable (in the sense that fatty acid soaps may not be formed), is clearly acted upon by alkalis to form a substance colloidally "soluble" in water. These substances are regarded as "protective colloids." There are a number of protective colloids that either do not occur commonly, or else are so invariably associated with unsaponifiable greases as to lose individual significance. Such substances are glue, gelatine, albumen, lecithin.

Temporary Globular Dispersion

To refer again to the "temporarily" emulsified globules, when agglomeration and attendent subsidence have proceeded as far as possible under the influence of gravity, an application of high centrifugal force will not cause additional agglomeration. A force higher than gravity will cause a correspondingly more rapid subsidence of agglomerated "temporary" globules, but the fixed concentration remains the same.

Similarly, an emulsion at its fixed concentration (or below) is favorably affected in one way by high centrifugal force—the subsidence of globules is more rapid. It is an interesting fact that the only variable in practice is in the rate of concentration. If the force is increased or diminished, the rate of concentration is correspondingly increased or diminished, but the residual emulsion is likely to be neither more nor less dilute, and the concentrated emulsion is likely to contain neither more nor less oil. In other words, for any given emulsion, the eventual yield is practically constant if the time during which centrifugal force (or gravity) is allowed to act is commensurate with the force applied. In order to increase the rate at which this yield may be obtained, it is sufficient to increase the force, but to increase the yield we must change the emulsion itself.

There is but one change that will increase the yield, and that is an increase in the size of the globules that remain in the dilute residual emulsion. In our use of the word "agglomeration" we have heretofore implied the union of globules to produce a continuous phase. However, agglomeration does not necessarily imply the production of a continuous phase. Almost any physical or chemical change in an emulsion will cause a change in the average and the minimum size of suspended particles, and this change is brought about by the union of several globules or else the splitting up to form smaller globules. It is only under peculiarly favorable circumstances that the change will go all the way to the limiting conditions of continuous oil on the one hand or "soluble" oil on the other hand. Ordinarily the change proceeds only part way—the globules become a little larger but they remain globules, or the globules become smaller but do not approach near enough to molecular dimensions to yield a transparent emulsoid.

Elimination of Protective Colloids

The most important factor in securing this partial agglomeration is a reaction to destroy the effect of the protective colloid. The reaction may not destroy the colloid itself, but it is sufficient to throw the colloid out of aqueous solution either by precipitation or extraction. Extraction may be accomplished by rendering the colloidal substance soluble in the oil of the emulsion. An impurity in the oil phase of a soap-water emulsion does not act as protective colloid. Agitation (within reasonable limits) tends rather to increase than to diminish the size of globules in a soap-water emulsion—an effect comparable to the production of butter from cream by churning. The addition of water will increase the size of the smallest globules.

The simplest chemical methods of causing agglomeration are based on the tendency of weak acids to "decompose" the alkaline protective colloids without splitting the soap. Carbon dioxide and boric acid are examples. The impurities when acidulated dissolve in the oil and thus greatly reduce the stability of the emulsion. It is natural to expect that the oil, when finally recovered, will be tainted with these impurities.

Any treatment based upon the elimination of the protective colloid is likely to be limited in its efficiency to the fixed concentration of the pure oil with a pure soap solution.

A condition that reduces the degree of dissociation of soap in solution will still further increase the yield of oil. As an example of such a condition the laboratory test may be cited where alcohol is added to a soap-water

emulsion to facilitate the separation of a petroleum-ether extraction.

Gelatinous Emulsions Persistent

Commercial soap-water emulsions commonly tend to gelatinize. Pure soap solutions will gel when the soap concentration is high enough, but the gel is rather unstable—a little addition of water or a moderate elevation of temperature is likely to destroy the gel to form a liquid of relatively low viscosity. The gels formed by many commercial soap-water emulsions are more stable. The emulsion is likely to retain its gelatinous character even after considerable dilution with water or the application of boiling temperatures. The stability of the gel appears to be largely influenced by the proportion of protective colloid present, for the non-fatty-acid greases in alkaline aqueous solution form persistent "semi-gels" not so rigid as a pure soap gel but much more stable. The impure industrial emulsion when gelatinous usually has this same persistent semi-gelatinous consistency.

The gelatinous character of an emulsion must be regarded as important in view of the fact that agglomeration to form a continuous oil phase and concentration of globules to form a saturated emulsion is impeded by high viscosity. The viscosity of these "semi-gels" is gradually reduced as the temperature is raised, but even when boiling, the emulsion is likely to retain gelatinous characteristics. The semi-gel can be truly liquefied only by dilution with water or by chemical action. When sufficient water has been added to eliminate gelatinous characteristics, the viscosity of the emulsion is not greatly influenced by temperature changes. The diluted emulsion will usually remain liquid under any circumstances of physical change, though a chemical change (such as that induced by the addition of a little salt) is likely to throw the emulsion back into the semi-gelatinous state. Conversely, when it is attempted to liquefy a gelatinous emulsion by chemical means (instead of dilution with water), the liquid state is likely to be quite unstable, and a reversion will occur with almost any physical change, such as heating or cooling, agitation, addition of small amounts of water, etc. The addition of a trace of mineral acid to a gelatinous emulsion will often cause liquefication. A little agitation will restore the gel. Another trace of acid again liquefies, and another agitation again causes reversion. This cycle may be repeated until the soap is nearly or completely decomposed.

A complex soap-water emulsion is rarely gelatinous, for the dispersed phase, when gelatinous, will readily settle out, yielding the excess of oil and the simple emulsion.

Effect of Dilution

Unless carefully prepared, a gelatinous soap-water emulsion will not contain its oil as suspended globules because the viscosity of the continuous soap solution is too high to permit interfacial surface tension to act. The oil will be in irregular streaks or strata. As soon, however, as the emulsion is liquefied by dilution or by other means, the oil assumes its globular form. In one sense, dilution reacts unfavorably on separation procedures, for dilution increases the stability that resists agglomeration. A gelatinous emulsion that will slowly yield up some of its oil in continuous form by agglomeration and subsidence will not yield this oil after dilution. In other words, some of the oil that is "temporarily" emulsified in the gel assumes the state of fixed globules when water is added. To reduce the percentage of oil permanently held up in gelatinous emulsions has been the subject of many a research.

It has been stated that when the concentration of soap, alkali and protective colloid is reduced, the fixed concentration of emulsified oil will be reduced. Whether or not dilution will cause a separation of oil from an emulsion depends, obviously, upon the mathematical structure of the function involving the variables of dilution and fixed oil percentage. To illustrate, suppose we take an emulsion which contains 10 per cent soap and 20 per cent fixed oil and 70 per cent water. The actual concentration of substances in the aqueous phase will therefore be 14.3 per cent soap, and 28.6 per cent oil. To 100 g. of this emulsion we add 70 g. water. The soap and oil concentrations will be cut in half—7.15 per cent soap and 14.3 per cent oil. If 14.3 per cent represents the fixed oil concentration for this diluted emulsion, we can recover no oil. If the fixed oil concentration is below 14.3 per cent, we can recover some oil. Suppose the value is 10 per cent. The fixed oil in grams will amount to 17. Our recovery will be 3 g., or 15 per cent of theoretical.

Often the fixed concentration will be reduced by larger differentials than the soap concentration up to a certain point beyond which the relation is reversed. The following table illustrates one case. The emulsion was composed as in the above paragraph. The emulsion was progressively diluted, and subjected to a given centrifugal force for a given period. The oil not recovered was regarded as "fixed."

Percentage of Aqueous Phase		Percentage
Soap Per Cent	"Fixed Oil" Per Cent	Recovery Per Cent
14.30	28.60	0
7.13	10.10	15
4.80	5.40	35
3.55	1.95	70
2.80	4.10	25
2.40	4.80	0

The above is an unusual case in that the dilution yielding maximum recovery is so low.

Recovery of Oil by Acidulation

The common method in our industries of recovering oil from soap-water emulsions is to acidulate. The acid reacts with the soap to produce fatty acids and the acid reacts also with the unstable alkaline organic impurities (when these are present). The impurities when acidulated are no longer protective colloids, but are usually quite soluble in oil and in fatty acid. When a commercial soap-water emulsion is acidulated, therefore, the recovered material consists of the mutually soluble oil, fatty acid and certain organic impurities that may have been present in collodial solution in the soap-water. We have seen one case in which the alkali-soluble non-fatty-acid material comprised more than 20 per cent of such an acidulated mixture.

The subsidence of the water-insoluble materials upon acidulation is usually rapid and complete because there exists no longer any soap or any alkaline protective colloid to stabilize the emulsion. Occasionally we run up against stubborn emulsions of fatty acid with dilute mineral acid, but these emulsions are totally different from the soap-water emulsion which constitutes the present subject for discussion. In cases where there is a tendency to form stable fatty-acid emulsions by the acidulation of soap-water emulsions, the stability depends very largely upon the physical conditions under which the acidulation is conducted. This is particularly

true when the alkali-soluble impurities form oil-insoluble solids when acidulated (wool-scouring liquors).

When it is considered satisfactory to obtain the mixture of oil, fatty acid and impurities, the acidulation of a soap-water emulsion is the obviously correct procedure —inexpensive, complete in yield and uniform in operation. The major reason, in fact, that acidulation is considered unsatisfactory is that methods of separation of oil, fatty acid and non-fatty-acid grease, each free from the others, have not received sufficient attention from chemists. The recognized methods for such a separation have involved new soap-water emulsions and yields are negligible.

Salting Out Processes

It is common knowledge that salt tends to throw soap out of aqueous solution. The higher the salt concentration the more complete will be the precipitation. Solutions of the soaps that are most easily salted will dissolve salt in low concentrations, without any actual precipitation. These low salt concentrations are interesting. Suppose we take a stable emulsion and add enough salt water to bring the salt concentration to 0.5 per cent of the aqueous phase. The usual effect will be the increase of stability. It will be more difficult to agglomerate globules or to concentrate globules without agglomeration. When a high concentration of salt is used, the soap will be thrown out of solution, and the oil may or may not be recoverable. This point is enlarged later on.

Breaking an Emulsion Without Precipitating Soap

But there is a certain point in salt concentration where a soap-water emulsion may be completely broken without an actual precipitation of soap, and the oil may be recovered as a continuous phase. It is believed that every soap-water emulsion (if not too viscous) will yield up some of its oil if exactly the right percentage of salt is carefully added, but the procedure is likely to remain an impractical laboratory curiosity on account of the difficulty in formulating any rule by which the correct salt percentage may be estimated. A series of tests on three commercial samples of cottonseed oil soap-water emulsions of nearly the same constitution in oil, soap and water gave the following salt concentrations as necessary for oil recovery—2.1 per cent, 3.6 per cent, 1.2 per cent. These concentrations are based on the water content of the emulsions. In each case when the salt concentration was increased or decreased by a few tenths of 1 per cent, the stability of the salted emulsion appeared much the same as the stability of the unsalted emulsion. This sensitiveness appears to be linked with the tendency for a soap-water emulsion to gel with slight provocation of chemical change. There was no gradual relationship between oil yield and salt concentration, but a sudden change at one definite point.

Moreover, there seemed to be no functional relationship between this point and the percentage of major constituents in the emulsion. A careful research would probably show that the critical salt concentration required to bring about this change is a somewhat complex function of all constituents—in particular the proportion of impurities that constitute the protective colloids. It would be helpful if a simple analytical determination could be devised to show what might be termed "effective alkalinity." Because of hydrolysis, soap solutions are always alkaline; but the alkali is often more loosely combined with the protective colloid than with fatty acid, so loosely, in fact, that it is possible to completely saponify a fixed oil in such an emulsion by the addition of normal sodium carbonate, which appears to displace the caustic alkali from the impurities. The protective colloid acts as a catalytic agent in a saponification of this sort. The non-fatty-acid organic material in colloidal solution may sometimes be extracted from an alkaline solution with ethyl ether or benzol.

The Critical Salt Concentrations

The effect of low salt concentrations on one emulsion is shown in the accompanying curve, (Fig. 1), wherein salt concentration is plotted against yield. The emulsion contained 75 per cent of a 25 per cent soap solution and about 20 per cent oil, with about 5 per cent alkali-soluble impurity. The yield figures represent the percentage of oil recovered as free oil based on a theoretical yield of 100 per cent, by subjecting the emulsion to high centrifugal force for a given period. The critical salt concentration is not nearly so sensitive with emulsions of cocoanut oil soap because this soap is more soluble than others in salt water. To revert to high salt concentrations, when soap is "salted out" the precipitation may occur in one of two ways—with a film of oil adhering to the soap particle, or with a similar film of water. When a salted emulsion is permitted to stand, or is centrifuged to permit immiscible layers to form, the salt water will be found at the bottom, the oil at the top and the soap particles intermediate. The soap layer is not a liquid layer, but a mass of solid particles with interstices occupied by liquid. Whether this liquid be oil or water will depend upon the character of the precipitation—whether the particles are enveloped by films of oil or of water. The settled system may therefore be considered as composed of only two layers—oil and water—with the soap sludge either in the upper portion of the water or else in the lower portion of the oil. (See Fig. 2.)

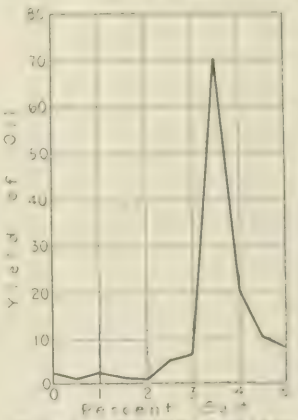

FIG. 1. CRITICAL SALT CONCENTRATION

It is clear that the yield of oil from such a separation is dependent upon the position of the soap sludge. It is highly important that the salting out be accomplished in such a manner as to suspend the soap in salt water. Unfortunately, no generally correct rules can be given here for a proper salting out. The writer has often been unable to secure an aqueous precipitation with some emulsions under any conditions. On the other hand, with other emulsions it has been found an easy matter to so alter the conditions of precipitation as to obtain the soap sludge either in the water or in the oil. An emulsion in which the ratio of oil to soap is high is particularly favorable to the aqueous suspension of the soap. The lower the soap concentration in the aqueous phase, the more likely the soap may be precipitated in the aqueous phase. The higher the concentration of protective colloids, the more likely the soap will be precipitated in the oil phase.

Often when an emulsion contains a high ratio of

soap to oil and an oil recovery by salting out appears impractical, it is feasible to concentrate the emulsion (after appropriate dilution) by gravity or preferably by centrifugal force and to salt out the saturated emulsion. The saturated emulsion contains more oil, less soap, and less organic impurities than does the original emulsion. But unless the soap and protective colloid concentration has been very materially reduced, it is necessary to dilute the saturated emulsion with fresh water to obtain a good yield of oil. The dilution aids the aqueous soap precipitation. When fresh water is added to an unsuccessfully salted emulsion the aqueous phase is diluted, but the soap still remains in the oil phase. In other words, the soap particles remain enveloped by the liquid originally in contact, no matter what changes are made *after precipitation.*

Any proper discussion of correct procedure for the addition of salt to a soap-water emulsion would lead us into the general problem of reactions between immiscible liquids. Such reactions are common in our industries, and the problem would seem to offer an interesting opportunity for further speculation and research. It is sufficient to remark here that emulsions sufficiently low in soap and organic impurities can be satisfactorily salted out by the addition of solid salt, if at least 30 per cent water is present in the emulsion. For water contents as low as 25 per cent, better results are secured by agitation with a saturated salt solution. For lower water contents, it is advisable to obtain a more thorough emulsification of brine with soap-water emulsion than can be ordinarily obtained with a stirring arrangement. A high velocity nozzle or a centrifugal emulsifier will accomplish this purpose.

If an emulsion is complex (i.e., contains some continuous oil), a dilution with fresh water will not greatly improve salting out conditions. Whether or not water is added to such an emulsion, a severe mechanical emulsification with brine is recommended.

The above data relate to sodium chloride. Other neutral salts of unit positive valence act similarly but in different degree. Sodium sulphate, for example, although not as effective as sodium chloride in the salting out of soap, accomplishes in general much the same results. A very low concentration of sulphate tends to stabilize an emulsion. Sodium sulphate has also its critical concentration where the emulsion is broken without soap precipitation, but the curve is apparently not as sharp as the curve shown for common salt. The writer has not noted the specific effect of high concentration of sodium sulphate.

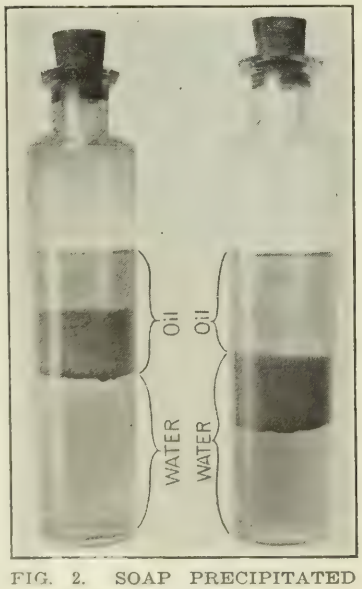

FIG. 2. SOAP PRECIPITATED IN THE OIL AND WATER PHASES

When a simple soap-water emulsion is chilled to a point where the continuous water is frozen, some of the emulsified oil is likely to agglomerate and separate after cautiously melting. This effect has been found to occur in cases of gelatinous emulsions high in soap and oil. The best method of freezing, the best methods of melting, the limiting conditions of emulsion composition and the yields obtainable under correct conditions are not known to the writer.

Simple emulsions of cocoanut oil give an opportunity of observing the opposite phenomenon. At normal temperatures the suspended oil is solid. No agglomeration of practical interest appears to occur when such an emulsion is alternately warmed and cooled except in cases of saturated emulsions, when a partial recovery may be made.

A mention of electrical separation methods will be in order.

Electrostatic Action

The various processes for a.c. and for d.c. current at high and low voltage, developed during the past decade for the separation of emulsions of water with crude petroleum, have proved highly successful in this field where large volumes must be handled at low costs (a few cents per barrel). Different investigators have ascribed different theories for "electrical precipitation," but from the nature of the processes one thing is self-evident—the action depends upon the dielectric property of petroleum, which is invariably continuous in these emulsions. The suspended water is affected by the current in such manner as to cause agglomeration and subsequent subsidence. If an aqueous phase were continuous, the current would be immediately short circuited, and there could be no conceivable agglomerating effect on the suspended dielectric oil.

Unless some entirely different method of electrical precipitation is developed, there would seem to be no possibility of separating oil by this means from a simple soap-water emulsion. On the other hand, there would seem to be no reason why the suspended emulsion in a complex soap-water emulsion could not be precipitated advantageously by means of a modified form of one of the present types of electric treater, because, in this case, the oil constitutes the primary continuous phase.

Perhaps some enterprising refiner of vegetable oils will some day develop an electrical system whereby an "off crude" may be refined with high yield.

In conclusion, we would call attention to an aspect of the soap-water emulsion problem that must be regarded as extremely important and that would require for proper discussion as much space as we have allowed for this entire article. When salts of multiple positive valence are added to a caustic alkali soap-water emulsion, a reaction takes place between the salt and the soap. The products of this reaction determine the stability of the emulsion.

We have attempted to describe and to define a viewpoint. The really difficult step in the development of a colloidal process is to interpret the problem and when an acceptable interpretation is forthcoming, it is not so difficult to find a satisfactory mode of operation. We believe that some of the data given above is rather more than less correct when applied to cases which we have specifically excluded. But if these data are regarded merely as an interpretation, you will not place any mistaken dependence upon what may have been expressed as a formula or rule. Each problem has its peculiarity, and generalizations are so infrequent that each specific case is likely to add to the sum of interesting but difficultly classifiable information.

The Acid Open-Hearth Process for the Manufacture of High-Grade Steel*

A Description of the Acid Open-Hearth Process Used at the Midvale Steel & Ordnance Co.'s Nicetown Works, and of the Conditions Conducive to the Successful Manufacture of High-Grade Steel

By B. E. L. deMARÉ

IN A broad sense, any steel which in a perfectly satisfactory manner serves the purpose for which it is intended may be considered high grade. In the more narrow sense, however, in which it is here used, it may be defined as a steel which, to be accepted, must pass certain more than ordinarily severe tests, where the margin between success and failure is so narrow and the financial loss by failure so great that the steel maker is not only justified but compelled to leave nothing undone which in any possible way may improve the quality of the steel, regardless of quantity or of any reasonable increase in its cost of manufacture, in order to insure a high percentage of acceptance when the steel is finally submitted to the test.

Products From Acid Open-Hearth Steel

The more important products of acid open-hearth steel, manufactured by Midvale, are as follows:

1. Armor-piercing projectiles,
2. Gun forgings, especially of large caliber,
3. Large or intricate forgings, such as marine crankshafts and connecting rods, bucket wheels and pinion shafts for steam turbines, and other forgings, in which transverse strength is required,
4. Forgings which require a hard and polished surface without flaw or blemish, such as hardened rolls,
5. Special grades of bar steel,
6. Locomotive and car-wheel tires.

The order in which the above classes have been enumerated may be considered as indicating the relative severity of the acceptance tests they have to pass, and therefore the relative degree of quality required, the armor-piercing projectiles requiring the highest quality, with gun forgings a close second, and so on.

Acceptance Tests

The test required for the acceptance of projectiles is as follows: From each lot of 500 projectiles four are selected to be fired against a face-hardened armor plate at a certain velocity and angle of impact, of which two must pass through the plate and remain in effective bursting condition. Should this test be a failure, four more projectiles may be selected and fired, of which three must pass through the plate and remain in effective bursting condition. In the case of 16-in. shells, the cost to the contractor of this second test would amount to about $20,000. Should it fail, the whole lot of 500 projectiles may be condemned; or the contractor may be permitted to re-treat it and re-submit it as a new lot, which would entail an extra expense of approximately $100,000. It is thus evident that every possible attention must be paid to the quality of this steel in order to avoid great financial loss, as well as loss in reputation.

Test for Forgings

The chief tests for acceptance of gun forgings are of the tangential test bars taken from the breech and muzzle ends of the rough-machined forgings. As specified, these shall be located with their axes in planes perpendicular to the major axis of the forging, and also with their axes perpendicular to the radii, which pass through the middle points of the lengths of the bars, and for larger gun forgings are to be taken, one from the outer, two from the middle and one from the inner section of wall at each end of the forging. The contractor will be allowed three official tests only. Where the test specimens fail to meet the requirements on the third submission, the piece shall be finally rejected, with certain exceptions.

The minimum physical qualities of nickel steel gun forgings of 3-in. caliber and above are as follows:

	T. S. lb. per sq.in.	L. L. lb. per sq.in.	Elong. Per Cent	Contr. Per Cent
Tubes and liners	90,000	55,000	18	30
Jackets	90,000	60,000	18	30
Hoops	95,000	65,000	15	30

Other causes for rejection of gun forgings are ghost-lines, where careful examination shows any lack of continuity of the metal, slag pockets and sand splits, or cavities containing particles of slag, etc., if, in the opinion of the inspector, they are serious enough. Bearing in mind that the present standard 16-in. 50-caliber Navy rifle is built up of forgings made from ingots up to 63 in. octagon in section and 200,000 lb. in weight, the importance of taking every possible care to avoid defects liable to cause their rejection may be appreciated.

What has been said of gun forgings applies in greater or less degree to the forgings mentioned in class 3, especially where transverse strength is required, as determined by transverse or tangential test bars.

Tests for Other Classes of Acid Open Hearth Steel Products

As regards the fourth class, such as hardened rolls, the difficulty with them is that after having been forged, annealed, machined, hardened, ground and polished, if then a careful inspection should reveal any imperfection in the polished surface, such as a small oxide or slag spot, hardly visible to the naked eye, this would condemn the roll as being unfit for its purpose.

In the remaining two classes, No. 5, special grades of bar steel, and No. 6, locomotive and car-wheel tires, we approach the borderland, where the acid and basic open-hearths compete, and where, except in a few cases, it is largely a matter of cost which one is to be pre-

*A paper read at the American Iron and Steel Institute meeting, May 28, 1920, New York City.

ferred, bearing in mind, however, that even in these classes, as far as quality is concerned, the acid product is superior to the basic, and therefore should command a higher price.

Acid vs. Basic Open-Hearth Steel

The superiority of acid over basic open-hearth steel, especially for any forgings depending on transverse test-bars for their acceptance, has been repeatedly proved, not only by our own experience, but by that of many others in this country as well as in England and France. Every attempt, for instance, to make heavy ordnance of basic open-hearth steel has from all accounts resulted in nothing but failure.

The reason for this is that the quality of the steel is measured by its freedom from oxides, and that acid open-hearth steel is more free from these oxides than basic steel, because acid open-hearth slag is more effective than basic slag by its reactions with the steel to de-oxidize it.

Of course, there is no open-hearth steel, acid or basic, absolutely free from oxides, nor is there any other steel, no matter by what process made, which under the microscope does not show oxide spots.

Therefore, oxidation is only a matter of degree, and the various processes overlap, so that a badly-melted steel, by whatever process produced, may be worse than a well-melted steel produced by any of the other processes. The claim that acid open-hearth steel is better than basic holds good only in so far as full advantage has been taken of the fact just mentioned in regard to acid slag, as compared with basic.

Ingot Defects Caused by Oxides

The effect on the ingot metal by this difference in the degree of oxidation is shown by the following facts:

1. The amount of deoxidizing finals just sufficient to produce an acid ingot free from blow-holes is not sufficient to make a basic ingot of similar composition solid, but will leave it decidedly blowy. For instance, tire-ingots, which are sliced in lathes into several blocks, and where therefore any lack of solidity in the ingot would be discovered, as the blocks are always carefully inspected just for such a defect, have proved beyond doubt that basic are much more liable to be blowy than acid tire-ingots, and that it is absolutely necessary to add more deoxidizing finals to basic than to acid heats, in order to make basic ingots as free from blow-holes as the acid ones. This proves that basic steel is more oxidized than acid steel. Consequently the greater amount of finals required for deoxidizing the basic steel, reacting with the greater amount of oxides in the steel, will produce a greater amount of the non-metallic impurities resulting from this reaction, chiefly silicates of manganese.

2. The ingot crystals of basic steel as shown by tire-ingots, as well as by numerous experiments with other grades of steel, are very much larger than those of acid steel, poured under the same conditions. For this reason and also because basic is more oxidized than acid steel, the finely divided oxides, still retained by the crystallizing steel and to a greater or less degree expelled by the growing crystals into the intercrystalline space, will thus form in the basic ingot a honeycomb of non-metallic impurities much more serious than in the acid ingot. The ferrite envelope surrounding the ingot grain, which marks the intercrystalline space as the ingot is cooled down, will also be far more distinct in size and outline in the basic ingot and harder to break up by subsequent forging and heat treatment, but even if this be eventually done, the non-metallic impurities will still remain and seriously affect the quality of the steel.

3. To bring out additional evidence as to the effect of ingot impurities on the internal structure of the ingot, a longitudinal cross-section may now be finish-machined and etched. As a result, there will appear certain dark lines symmetrically disposed on either side of the center line, and running in an oblique direction inward and upward. These lines are the paths taken by metallic segregations high in phosphorus and sulphur, mixed with silicates and sulphides of manganese, resulting from the reactions in the steel after it has been poured into the mold. These impurities remain fluid during the time of crystallization, part of them becoming entangled among the ingrowing crystals, while the rest are driven inward by the solidifying shell, and upward on account of being lighter than the surrounding mother metal, and as they progress toward the center and top of the ingot they coalesce into larger and larger globules and increase more and more in number. They may later be identified in the forging made from the ingot, the metallic segregations high in phosphorus and sulphur as "ghostlines," especially in the bore of hollow forgings, and the silicates of manganese as "slag pockets" or "sand splits" in the machined forging, and also as streaks of "slag" across transverse test bars.

Composition of Ghostlines

The composition of the "ghostlines" was determined at Midvale some years ago by slicing a transverse section off the end of a large hollow forging, made from an ingot which had been cast in a sand-lined mold and which therefore had a great many well-defined "ghostlines" in the bore. On etching this section the "ghostlines" were plainly seen as bright spots, increasing in number from the outside to the bore. These spots were drilled with a $\frac{3}{32}$-in. drill, and the drillings, as well as the surrounding metal, analyzed with the following result:

	Per Cent C	Per Cent Mn	Per Cent P	Per Cent S	Per Cent Si
Ghostlines	0.497	1.026	0.082	0.116	0.268
Surrounding metal	0.498	0.894	0.030	0.047	0.316

In regard to the silicate of manganese, opportunity was offered for its analysis by finding a large quantity that had escaped to the bottom of the shrinkage cavity in a 63-in. octagon ingot of basic steel which had had the usual finals for this kind of steel of ferromanganese, ferrosilicon and aluminum. The lower part of this silicate was a yellow-blue, solid enamel, while the upper part was very light and porous, and violet-blue and black in color. The compositions were:

	Per Cent SiO_2	Per Cent MnO	Per Cent Al_2O_3	Per Cent FeO, etc.
Lower part	51.60	40.60	7.88	trace
Upper part	50.34	29.94	18.90	trace

The defects in the steel resulting from these lines of ingot impurities will be necessarily more serious in basic steel than in acid, specially in regard to the oxides.

The much less serious effect of the segregations high in phosphorus and sulphur, which are the cause of ghostlines, may be modified in basic steel because of the fact that this, as a rule, is lower in phosphorus and sulphur than acid.

Other points considered here are:

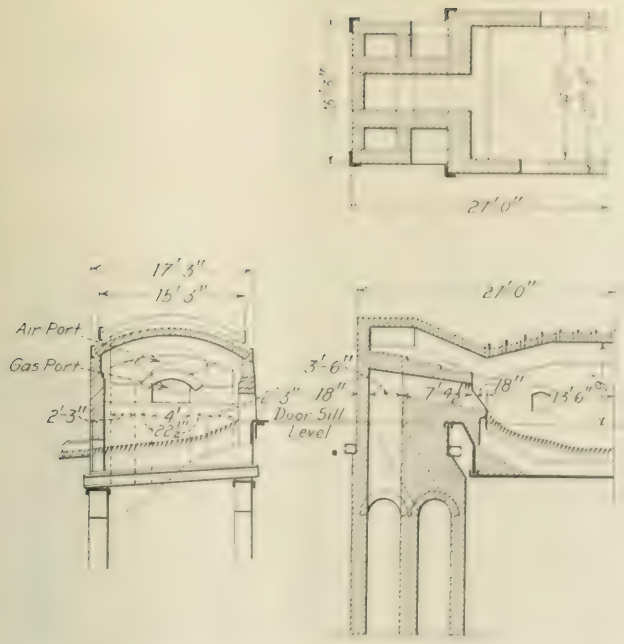

FIG. 1. 50-TON OPEN-HEARTH FURNACE, PRODUCER GAS AS FUEL

The proper design of the furnace for high-grade acid open-hearth steel.

A comparison between producer gas and fuel oil for melting.

An analytical description of the acid open-hearth process as carried out by Midvale.

Proper Furnace for High-Grade Acid Open-Hearth Steel

Two designs of open-hearth furnaces are shown, one as adapted for producer gas (Fig. 1) and the other for fuel oil (Fig. 2). The nominal capacity of both is fifty tons, although charges up to 140,000 lb. may be melted. There is nothing peculiar in the designs, as far as valves, flues, regenerative chambers or stacks are concerned, and these parts are therefore not shown. The only unusual feature is the great height of the furnace roof over the doorsill level. This has been a gradual development, and has been found advantageous on account of the high and long sustained temperature necessary to carry out the chemical reactions during the deoxidizing period of the process. The high roof provides a large combustion chamber, which permits a full and free development of the flame, and at the same time avoids damage by the intense heat to the roof and walls of the hearth. Even so, it is advisable with a new furnace to keep it working a few weeks on the less exacting grades of steel, such as tires and bar steel, in order to harden it, before turning it over on the higher grades, as not even the best quality of silica brick will stand at the beginning the high temperature required for these. Toward the end of its life the furnace as a general rule has again to be put back on lower grades of steel, as on account of impaired condition of checkers and draught it is no longer sharp enough for making high-grade steel.

No water-cooled devices of any kind are used in the walls, roof or ports of the furnace, as it has been found as a result of many trials that even when used to a very limited extent their cooling effect interferes with the sharp working of the furnace. The only water-cooled parts used are the charging doors, as they are far enough removed from the interior not to have a noticeable effect on the heat.

It may be of interest to give here a comparison between the life of acid and basic open-hearth furnaces, when melting with producer gas as well as with fuel oil, as measured by the average number of months from the time of charging the first heat after a general repair, until the time of tapping the last heat before the next general repair. The average number of months is given rather than the average number of heats on account of the great variety of heats made, some requiring twice as long a time as others, and the comparison is based on our records for the last five years.

AVERAGE LIFE OF OPEN-HEARTH FURNACES

	Months
Basic furnaces on producer gas	9.1
Basic furnaces on fuel oil	10.7
Acid furnaces on producer gas	11.2
Acid furnaces on fuel oil	12.8

Producer Gas and Oil as Fuel

Just as good steel can be made with producer gas as with oil as fuel, and vice versa. Oil is more oxidizing than gas and therefore requires a greater proportion of pig iron in the first charge and a higher temperature after the heat is melted to settle up the metal. On the other hand, oil cuts down the repair cost, requires fewer men per furnace, increases the production, permits better control of temperature, and extends that part of the life of the furnace which is available for making high-grade steel almost to the very end, as the direction of its flame is controlled from the outside and it is less affected by the condition of checkers and draught for generating a high temperature.

Taken all in all, oil is, therefore, much to be preferred as long as its price is not prohibitive.

Analytical Description of a Heat for Acid Open-Hearth Steel

The heat considered here, which is marked MK-13-126, was made for steam turbine bucket wheels, which

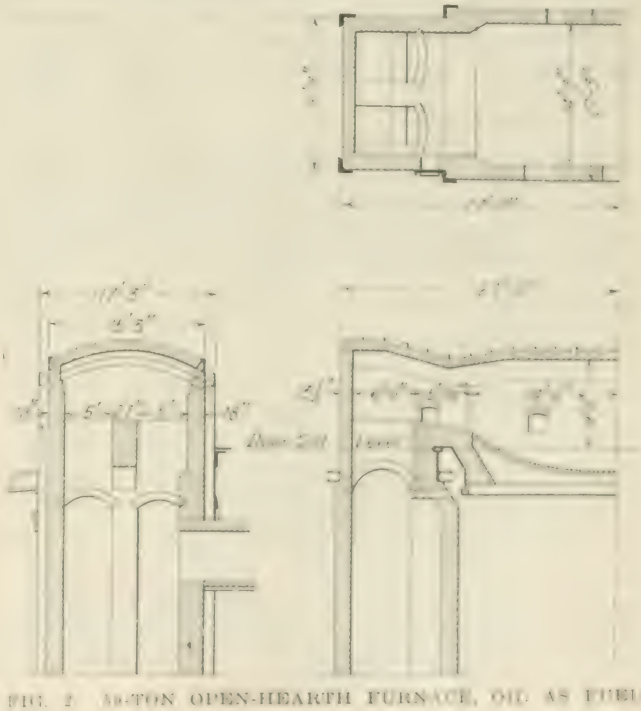

FIG. 2. 50-TON OPEN-HEARTH FURNACE, OIL AS FUEL

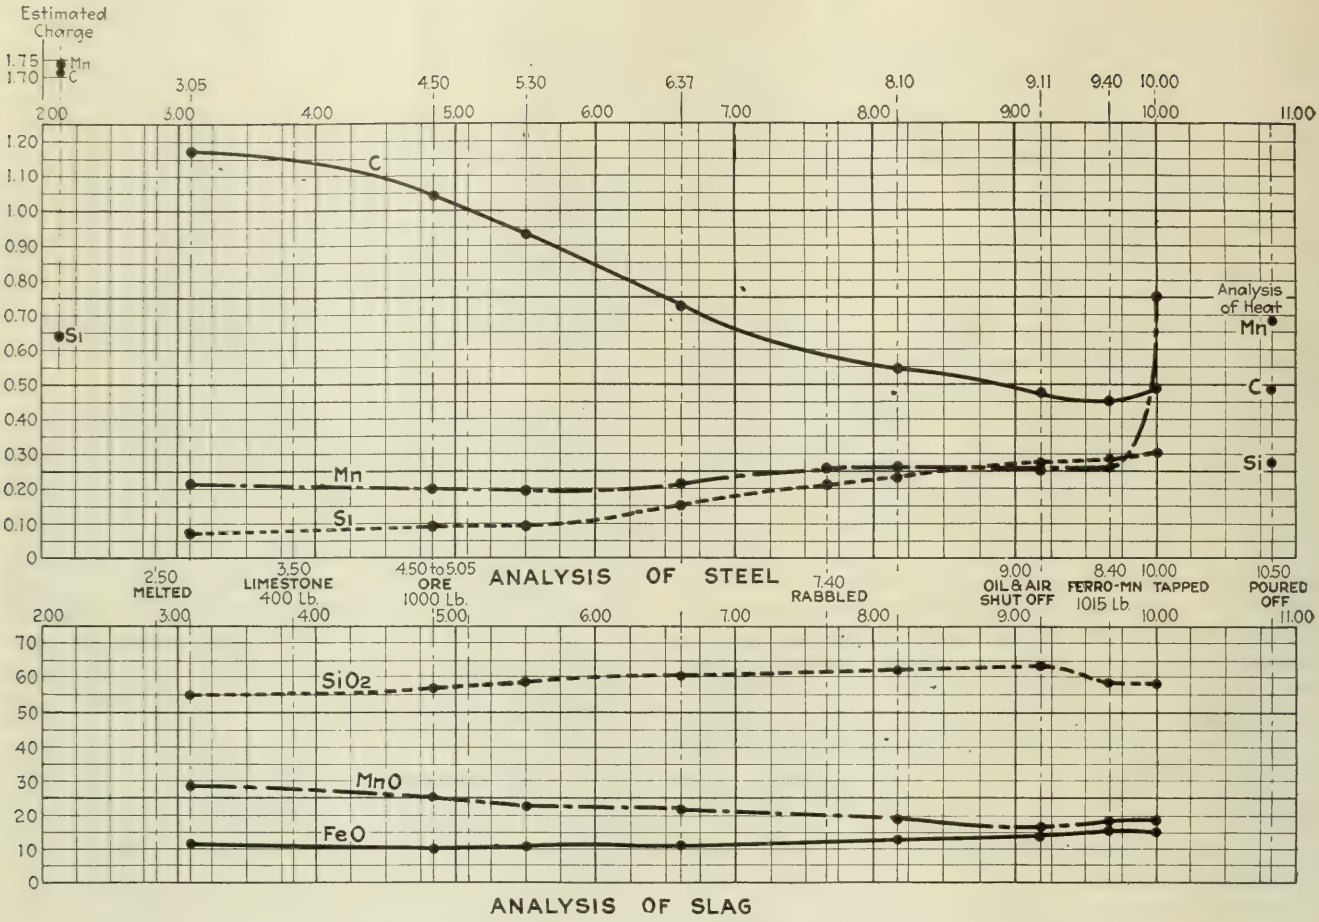

FIG. 3. GRAPHICAL ANALYSIS OF AN ACID OPEN-HEARTH HEAT NO. MK-13-126

require tangential strength, and therefore their acceptance depends on physical properties as shown by tangential test bars. Hence, high-grade acid open-hearth steel is used for their manufacture.

It is a simple heat of plain carbon steel and its treatment is typical of the class of steel to which it belongs. Though not especially selected for this analysis, it may be considered a good, clean heat, without unnecessary complications, and is therefore suitable to illustrate the principles followed in the treatment of the highest grade of steel.

The initial charge of 141,000 lb. melted in a 50-ton acid furnace of the design shown consisted of 35 per cent of pig iron and 65 per cent of scrap. The estimated carbon, manganese and silicon in the charge were C 1.72 per cent, Mn 1.74 per cent, Si 0.64 per cent. Time consumed for heat in furnace follows:

	Hr.	Min.
Time of charging (in two periods)	1	45
Time of melting	5	50
Time in furnace after melting	7	10
Total time in furnace	14	45

The history of the heat, after the initial charge was melted, may be thus summarized:

hr. 0 min. after melted, addition of 400 lb. limestone.
hr. 0 min. after melted, addition of 1,000 lb. iron ore
hr. 50 min. after melted, bath thoroughly rabbled.
" 10 min. after melted, oil and air shut off.
" 50 min. after melted, addition of 1,015 lb. ferromanganese.
" 10 min. after melted, heat tapped
hr. 9 min. after melted, heat poured off.

The analysis of the go-ahead test, taken 1 hr. 10 min. before tapping, and the C, Mn and Si obtained from 1,015 lb. of ferromanganese added 20 min. before tapping are shown in the following table:

	C	Mn	Si
Analysis of go-ahead test	0.49	0.27	0.24 *
Addition of ferromanganese	0.05	0.57	0.01
Total	0.54	0.84	0.25

* Judged by fracture.

The table below shows the chemical composition of the heat as aimed at, and as obtained:

Composition	C	Mn	P	S	Si
Aimed at	0.50	0.65	0.050	0.050	0.25
Obtained	0.49	0.68	0.036	0.038	0.27

On account of the high percentage of Mn in the initial charge the slag remained greenish yellow in color from the time the heat was melted until it was tapped, with only slight variations in shade.

The steel was poured into 23-in. octagon molds, 9 ingots of 10,500 lb., and 3 ingots of 11,400 lb. weight. The ingots, after cooling, were sent to the machine shop to be sliced into blocks, and these blocks were then forged under a steam hammer into bucket wheels for steam turbines.

To facilitate the analytical description of this heat, a graphical analysis chart has been plotted and drawn, showing its chemistry from the time it was melted at 2:50 a.m. until it was tapped at 10 a.m. (Fig. 3).

Eight breaking tests were taken at various times and poured into a standard test mold, about 2 in. deep x 2 in. wide x 6 in. long. These tests were broken and each fracture photographed. At the same time other tests were taken, both of steel and slag, for chemical analysis.

The steel tests were analyzed for C, Mn and Si, and by plotting these determinations on the "Analysis of Steel" chart, curves were obtained showing the changes in these elements.

The slag tests were analyzed for SiO_2, MnO, FeO, Fe_2O_3, CaO, MgO, Cr_2O_3, and Al_2O_3, but to avoid confusion only the three most important of these oxides, SiO_2, MnO and FeO, were plotted on the "Analysis of Slag" chart, to show the changes taking place in the composition of the slag during the progress of the heat. The full analysis of each slag test is:

SLAGS FROM M.K.-13-126

	SiO_2	MnO	FeO*	Fe_2O_3*	CaO	Cr_2O_3	Al_2O_3	MgO	MnO FeO Fe_2O_3 CaO	Total
1	55.0	28.0	11.1	1.4	2.6	0.3	1.4	0.6	43.1	100.4
2	57.0	25.0	10.3	0.6	3.9	0.3	1.4	0.6	39.8	99.1
3	58.7	22.7	11.0	0.7	3.9	0.2	1.9	0.8	37.9	99.9
4	60.7	21.3	10.5	0.9	3.3	0.2	1.5	0.8	36.0	99.3
5	62.2	18.7	12.7	1.0	2.5	0.2	1.5	0.7	34.9	99.5
6	63.0	16.5	13.9	0.9	2.5	0.2	1.5	0.5	33.8	99.0
7	58.5	18.0	15.5	2.1	2.4	0.2	1.6	0.6	38.0	98.9
8	58.4	18.8	15.0	0.4	2.4	0.2	1.5	0.5	36.6	97.2

Test No. 1

Commencing with test No. 1, taken at 3:05 a.m., or 15 min. after the heat was melted, its analysis shows the oxidation of C, Mn and Si during the time of melting by comparing it with the estimated percentage of these three elements in the initial charge. C has dropped from 1.72 to 1.17 per cent, Mn from 1.74 to 0.21 per cent, and Si from 0.64 to 0.07 per cent. A considerable percentage of Mn in the first charge is highly desirable, because by its oxidation during the melting it gives a clean slag, greenish yellow in color, almost from the start, and if the pig iron doesn't contain enough Mn, this deficit is made up for high-grade steel by the addition of ferromanganese to the initial charge. A high percentage of both Mn and Si is also desirable in the initial charge on account of their oxidation being an exothermic reaction, facilitating the melting and giving a bath hotter and less sluggish with iron oxide by the time the charge is melted. Both these elements oxidizing at a lower temperature than carbon, their oxidation, as far as it goes, is practically complete by the time the charge is melted, while the carbon is still comparatively high.

Care is now necessary in the addition of iron ore for de-carburizing the metal, as this is an endothermic reaction, absorbing heat and requiring a high degree of temperature for a vigorous reaction between the oxygen of the ore and the carbon of the steel. If the addition of ore is made too soon, or in too large a quantity, its chilling effect may so retard this reaction that when finally the high temperature required is reached and the bath goes into a boil, this will carry the decarburization so far that by the time the bath is well settled up the carbon in the steel is well below the carbon aimed at. This would necessitate additions of spiegel and pig iron in order to recarburize the heat. Such a condition is almost fatal to the production of high-grade steel, because the lower the carbon in the go-ahead test as compared with the carbon aimed at and therefore the greater the addition of recarburizing finals, the greater will be the amount of silicate of manganese produced. This may quite likely lead later on to the condemnation of the forgings made from such a heat on account of "sand-splits" or "slag-enclosures," or on account of transverse test bars failing in extension and contraction, due to streaks of "greenish slag" or "woody structure" caused by these streaks, or, in the case of projectiles, on account of cracks starting from small slag enclosures during the hardening process, or on account of the projectiles selected for the firing test, breaking up in striking the face hardened armor on account of the weakening effect of these concealed impurities.

Hence the reason for the note on the melting order: "Add no ore until 2 hr. after melted." Except steadily increasing the temperature of the heat during these 2 hr., the only thing done was the addition of 400 lb. of limestone 1 hr. after the charge was melted. By displacing a certain amount of iron oxide in the slag and making it more fluid, the limestone seems to put it in a better condition for subsequent reactions, at least where there is a low manganese content in the initial charge.

This, however, is, in my opinion, the only time when addition of lime is of any value. If done later during the de-oxidizing period of the heat, it will simply undo all the good that has been done, because replacing the FeO in the slag then will drive this into the steel to oxidize the silicon and manganese and make the bath again raw and unsettled.

Tests Nos. 2, 3, 4 and 5

At the end of two hours, test No. 2 was taken. This shows the oxidation of the carbon, slow at first on account of lack in temperature, now well under way. There having been as yet no addition of iron ore, this oxidation is caused by the rust in the initial charge, by oxidation of the charge in melting and by the oxidizing effect of the flame itself.

The higher temperature of the slag is also shown by its slightly higher percentage of SiO_2.

Test No. 3, taken 40 min. after No. 2, shows the oxidation still going at the same rate, due to the addition of 1,000 lb. of iron ore during the interval. The only effect of this addition on the slag is a slight increase in FeO, the SiO_2 continuing to rise and the MnO slowly decreasing by dilution with the SiO_2 taken up by the slag from the bottom along the slag line.

Test No. 4, taken 1 hr. and 7 min. after No. 3, shows the oxidizing period at an end. The SiO_2 in the slag has now gone up from 55.0 per cent, 15 min. after the heat was melted, to 60.7 per cent, while the two chief bases, MnO and FeO, have dropped from a total of 39.1 per cent to 31.8 per cent, in spite of the lower carbon in the steel. But most marked and showing that the de-oxidizing period has set in, is the increased percentage of Si in the steel, caused by the reaction between the carbon of the steel and the SiO_2 of the slag, according to the formula:

$$2C + SiO_2 = Si + 2CO.$$

Whereas during the melting of the charge on account of the low temperature then prevailing, the oxidation of Si was going on at a much greater rate than the oxidation of the carbon, with the steadily increasing temperature this oxidation of Si was first checked, then held, until finally a complete reversal has taken place, the very high temperature now reached having so increased the affinity of carbon for oxygen that it is able to reduce Si out of SiO_2, leaving the Si free, in its nascent and therefore most efficient state, to de-oxidize the steel, as shown by the increasing solidity and freedom from blow-holes of subsequent tests. This reaction is the essential point that accounts for the difference between acid and basic steel and that which makes acid steel superior to basic.

What has just been said in regard to the effect of the increased temperature on the relative affinity of C and Si for oxygen is also shown to have taken place in the relative affinity of C and Mn for oxygen, the C now

*Any metallic Fe present was determined as FeO. This would result in a high figure for FeO and a low figure for Fe_2O_3.

reducing Mn out of the MnO of the slag, the nascent Mn also assisting in the de-oxidation of the steel. This manganese reaction, however, which also may take place in a basic open-hearth heat, is much less effective than Si in de-oxidizing the steel, because the de-oxidizing effect of Mn is much less than that of Si, the latter, according to Brinell, being 5.2 times more effective than the former.

Test No. 5 shows the characteristic "worm-holes" well developed from the increased absorption of Si, which has gone up to 0.23 per cent. The only thing done with the heat between tests Nos. 4 and 5 was to give the bath a thorough rabbling with steel bars to facilitate the liberation of gas. Nothing else is now being done except to keep on pushing the temperature higher and higher to promote the reaction between C and SiO_2.

The reason why the carbon curve is still on a downward slope, in spite of the now well-settled-up condition of the bath, is no longer the reaction between the iron oxide of the slag and the carbon of the steel, which occurred during the oxidizing period of the heat, but the reactions of the de-oxidizing period between the carbon in the steel and the SiO_2 and the MnO of the slag, the Si and Mn, as previously explained, being constantly reduced to act as carriers in de-oxidizing the steel, while the CO resulting from this reaction bubbles slowly up through the slag. Assuming that when No. 5 test was taken the percentages of Si and Mn in the steel were the same as when No. 3 test was taken, it may be shown by a simple calculation that the carbon then would have been about 0.67 per cent, instead of having dropped to 0.54 per cent, so that but for this later reaction of the de-oxidizing period the carbon line would have been almost horizontal.

Tests Nos. 6, 7 and 8

Test No. 6 shows the de-oxidizing process almost complete, the "worm-holes" of the previous test having been nearly obliterated by the steadily increasing percentage of Si. The heat would now have been ready for the final addition of ferromanganese made just before tapping, except for the fact that the carbon, according to the first go-ahead test, was still a little too high or 0.53 per cent. A second go-ahead test had therefore been taken out 10 min. ahead of test No. 6, and on this being reported as being down to 0.49 per cent carbon the ferromanganese was added at 9:40 a.m., and the heat tapped at 10 a.m., or 20 min. later.

Test No. 7, taken just before adding the ferromanganese, is very little different in appearance from test No. 6, while test No. 8, taken after the addition of ferromanganese and just before tapping the heat, is absolutely solid. The Si in this test was 0.30 per cent, while the Si in the heat test, taken while pouring the steel into the molds, was 0.27 per cent, which shows that the Si in the steel while still in the furnace is higher in the stratum close to the slag, from which test No. 8 was taken and where the reduction of Si from the slag is taking place, than the average Si of the whole mass of steel.

Aluminum and titanium are never used for de-oxidizing steel in which transverse strength, as determined by transverse tests, is required, because the oxides of these elements have a very baneful effect on the physical properties of such tests, even when used very sparingly. It is difficult to believe, but it is nevertheless a fact, that this effect of aluminum, added into the ladle at the rate of 1 lb. of aluminum to 10,000 lb. of steel and held 25 min. before pouring, very likely will cause the condemnation, on account of failing test bars, of a gun forging made from this steel.

Influence of Shutting Off the Fuel and Air 1 Hr. Before Tapping

There is one more point in regard to the chemistry of this heat that requires an explanation. That is the shutting off of the oil and air, which also implies the lowering of the stack-damper, 1 hr. before tapping.

It may be noticed on the "Analysis of Steel" chart that this had no effect on the C, Mn and Si curves. On the "Analysis of Slag" chart, however, the result was a sudden drop in the SiO_2 curve, and a corresponding, but less marked, rise in the MnO and FeO curves. This, of course, does not mean a loss of SiO_2, as far as the actual weight of this oxide in the slag is concerned. What has occurred is an absorption by the slag of an additional amount of the two basic oxides, MnO and FeO, from some source, thus making the slag less acid than it was before.

The thermal effect was a very decided cooling of the slag, while, on account of slag being a poor heat-conductor, the temperature of the steel underneath the slag was by comparison only slightly lowered.

The reasoning which first led me to try this treatment with the point in view of still further de-oxidizing the steel was this:

As the temperature of an acid heat rises, by degrees de-oxidizing the bath through the reactions between the slag and the steel made possible by this rise in temperature, a point is finally reached where this reaction has to be stopped, in order not to get the steel too high in Si. If at that point the furnace were suddenly cooled by shutting off the flame, the effect would be a sudden cooling of the slag, while the temperature of steel, protected from radiation of heat by the blanket of slag, would be only slightly affected. This thermal change would have the effect on the slag of considerably increasing its affinity for basic oxides. The only supply of these oxides then available would be the traces still retained by the steel, which would therefore to a greater or less degree be absorbed by the slag. On account of the weight of slag in a heat being only about 7 per cent, while the steel makes up about 93 per cent, or thirteen times the weight of slag, a trace of oxides in the steel if absorbed by the slag would be quite a noticeable amount.

This, I believe, is the explanation of the change in the composition of the slag, resulting from shutting off oil and air for 1 hr. before tapping. This treatment was first tried more than seventeen years ago, since which time it has been in continuous use, especially in the case of carbon and nickel steel for large ingots.

The cooling effect on the steel, although slight compared with that on the slag, is also advantageous in order to lower the temperature for pouring large ingots, as otherwise the high temperature of the steel would make the ingots pull badly in forging. For this reason the steel is still further cooled by holding it from 20 to 30 min. in the ladle before starting to pour.

This ends the difference in the treatment of acid from that of basic open-hearth steel. I only want to add that though this treatment is simple enough, it requires great skill and good judgment on the part of the men in the shop, and that uniformly good results can be obtained only by careful and intelligent men after many years of training.

Similarity of the Magnetic Change in Cementite and Ferrite

By Miss H. G. Movius and Howard Scott *

THE purpose of this paper is to present evidence that the transformation of cementite from the paramagnetic to the non-magnetic state is accompanied by a detectible thermal effect similar to that accompanying the corresponding transition in pure iron. This behavior of cementite as exhibited in steels and cast iron, in which the carbon is in the form of free cementite in its ferrite matrix, was probably discovered by Wologdine[1] and has been studied by means of magnetic methods by Honda[2] and by Smith[3].

Separating the cementite from its matrix of ferrite, its transformation has been studied by Honda and Murakami[4] and by Ishiwara[5]. Honda and Murakami, by means of this method, determined the critical temperature of this transformation of cementite, which they call Ao, to be 215 deg. C., the critical temperature being defined as the temperature at which the transformation ends on heating and begins on cooling.

Chevenard[6] has detected this transformation in steel by means of expansivity measurements and Iitaka[7] by means of resistance measurements.

By obtaining differential cooling curves on white pig iron, Honda and Takagi[8] have shown an obtuse inflection in the neighborhood of 200 deg. C.

The changes in the physical properties of cementite measured by the above-mentioned authors show a strong resemblance between the magnetic transformation of cementite and that of ferrite, so it is not surprising that this resemblance persists in the behavior of the material upon heating as detected by thermal analysis and reported here. For the purpose of the comparison, thermal curves were taken by the inverse rate method in the manner recently described[1]. The materials studied were a pure iron, a eutectoid carbon steel and a 1.94 carbon iron-carbon alloy of the composition given in Table I.

The pure iron and iron-carbon alloy were prepared as described in Bureau of Standards Scientific Paper 266, and hence any impurities other than those given in the table are present only in minute quantities; the total impurities are probably less than 0.04 per cent.

The thermal curves, in which the behavior of the material of these three compositions when heated over the temperature range 100 to 300 deg. C. is recorded, are shown in Fig. 1, while Fig. 2 shows those of the pure iron when heated over the A_2 range. The steels were in the pearlite state and no graphite was present in the 1.94 C steel. It may be noted from the curves that the intensity of the Ao transformation in the 1.94 carbon steel is small in comparison with A_2 of the pure iron, but that it has the same distinguishing characteristics, that is, a gradual approach to the maximum, a lack of definite hysteresis between the maximum on heating and on cooling, and a difference in form between the Ac and Ar inflections which the curve for pure iron shows very clearly. For the sensitivity of the apparatus employed, the transformation Ao is only barely perceptible in the 0.95 carbon steel and cannot be detected in instances where vibrations of the building and other extraneous influences mask the heat effect. The inflection, of course, is not visible in the pure iron curve, which has been plotted mainly to show the furnace characteristics over the temperature range investigated. The intensity of the curve inflection of Ao can be magnified by choice of a more sensitive thermocouple if so desired.

The temperature values of the maximum thermal inflection, as noted on the curves, are given in Table II

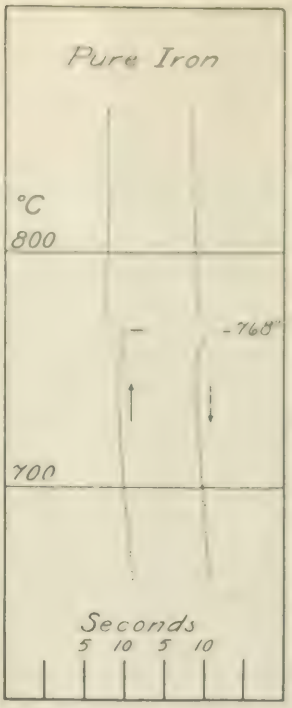

FIG. 2. THERMAL CURVES OF PURE IRON IN REGION OF A_2 TRANSFORMATION

TABLE I. CHEMICAL COMPOSITION OF STEELS

	C	Mn	Si	S	P
Pure iron	0.03	0.005	0.005	0.005	
Eutectoid steel	0.95	0.22	0.24	0.01	0.01
Pure iron-carbon alloy	1.94		0.01	0.005	

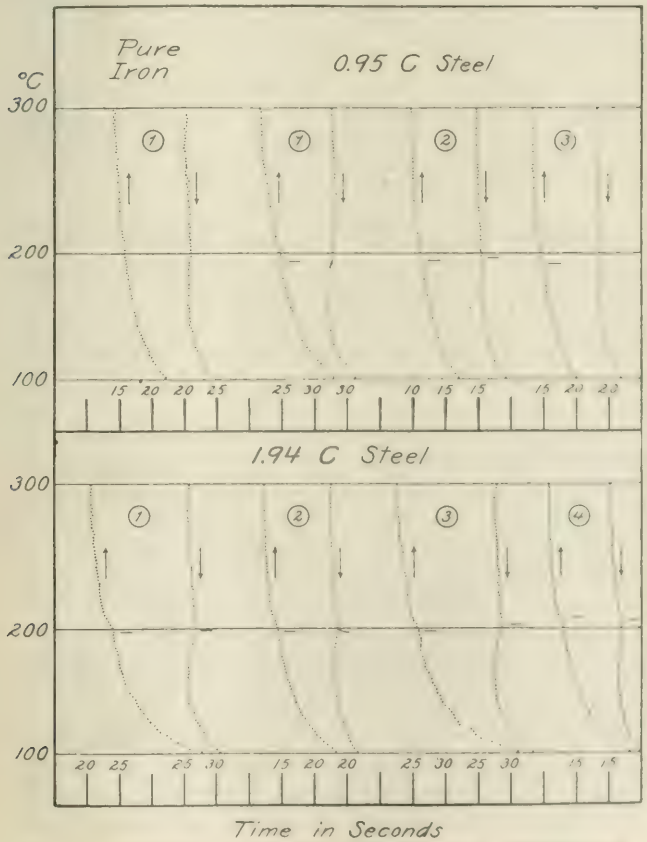

FIG. 1. THERMAL CURVES IN REGION OF CEMENTITE TRANSFORMATION

*Published by permission of the Director, Bureau of Standards.

[1]Wologdine: *Compt. Rend.*, vol. 148, p. 776 (1909).

[2]Honda, *Sci. Rep.*, Tohoku Imp. Univ., vol. 2, p. 203 (1913). Honda & Takagi, *Ibid.*, vol. 4, p. 161 (1915). Honda, *Ibid.*, vol. 6, p. 149 (1917).

[3]Smith: *Proc.* Phys. Soc. of London, vol. 25, p. 77 (1912).

[4]Honda & Murakami, *Sci. Rep.*, Tohoku Imp. Univ., vol. 6, p. 23 (1917).

[5]Ishiwara, *Ibid.*, vol. 6, p. 285 (1918).

[8]Honda and Takagi, *Sci. Rep.*, Tohoku Imp. Univ., vol. 4, p. 161 (1915).

From this table it appears that the maximum of the transformation occurs at a slightly higher temperature in the higher carbon and steel in which the manganese and silicon are practically nil and that in this case its temperature is in the neighborhood of 200 deg. C. Rate of temperature change has no appreciable effect over the range of rates used on its position, as is also the case with A_2 of pure iron[10].

The difference between the temperature given by Honda (215 deg. C.) and the one given here (200 deg. C.) for Ao does not imply an experimental error in

TABLE II. TEMPERATURES OF CRITICAL POINT OF CEMENTITE

Per Cent C	Curve No.	Rate of Heating Deg. C. per Sec.	Aco Deg. C.	Rate of Cooling Deg. C. per Sec.	Aro Deg. C.
0.95	1	0.09	194	0.08	...
0.95	2	0.16	191	0.12	...
0.95	3	0.21	192	0.14	194
1.94	1	0.10	198	0.09	199
1.94	2	0.18	199	0.12	200
1.94	3	0.09	199	0.08	202
....	4	0.19	207	0.14	205

either case, for the values are taken as previously defined from non-coincident points on curves which represent a transformation of the continuous type.

Thermal curves taken on a eutectoid and a 1.94 carbon steel show the magnetic transformation of cementite in both, but more marked in the latter. It has the thermal characteristics peculiar to the A_2 transformation of pure iron and occurs as a maximum in the pure iron-carbon alloy at approximately 200 deg. C.

The thermal change at Ao for the carbon tool steel is so small as to be hardly discernible and consequently cannot be confused with the thermal phenomenon observed on heating hardened steels through the same temperature range.

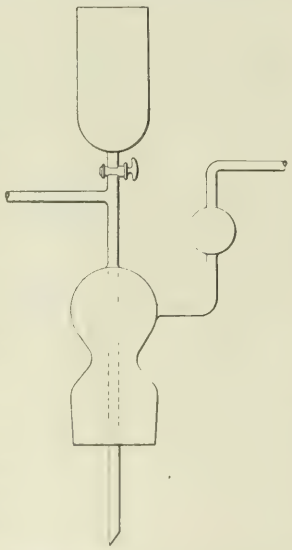
Special Gas Wash-Bottle for Use in the Referee's Test for Sulphur

By A. E. Maze*

In the referee's test for total sulphur in gases the gas is burned in a suitable burner, where the sulphur is converted to sulphur dioxide. The products of combustion are carried into a series of wash bottles containing an alkaline solution of bromine, where sulphur dioxide is absorbed and oxidized to sulphuric acid. If sufficient bromine is added at the beginning to suffice for the entire test a very large excess must be used. To keep the bromine consumption at a minimum only a slight excess is added at the beginning and the bromine is replenished from time to time. To maintain the flame in the burner considerable suction must be applied to the wash bottles. In adding bromine the bottle nearest the burner is opened and in this way the draft is interrupted and frequently the flame is extinguished. At times this may not be noted for some time and the test rendered useless.



To eliminate this difficulty a wash-bottle having a funnel and cock in the inlet is placed directly after the burner. The figure represents the top of such a wash-bottle. Through this funnel the bromine may be added in required quantities without interrupting the draft or endangering the flame.

Hydro-electric Power Development in France

The hydro-electric resources of France are estimated at from 8,000,000 to 10,000,000 hp., about 4,000,000 of which is in the regions of the Alps; in Massif Central, Vosges, and Jura, 1,500,000; in Pyrenees, 1,700,000; and in other regions, 800,000. Between 1869 and 1899, 150,000 hp. was developed. In September, 1902, statistics presented at a water-power congress held at Grenoble showed that 200,000 hp. had been developed. After 1902 development progressed as follows: By 1905 there was a total of 450,000 hp.; by 1910, 650,000; by 1913, 750,000; by 1914, 800,000.

Between 1916 and 1918 it was estimated that 450,000 hp. was developed, bringing the total development up to the time of the armistice to 1,250,000 hp. Projects started in 1919, totaling 175,000 hp., and projects planned for construction in 1920-1921, developing 225,000 hp., will bring the total development in 1921 to 1,650,000 hp., or about 20 per cent of the total available.

The power development between the end of 1915 and 1921, about 850,000 hp., is divided among the several regions as follows: Alps, 428,000 hp., Pyrenees, 185,000; central France, 200,000; Jura and Vosges, 35,000; West, 2,000.

Thus it will be seen that nearly 50 per cent of the power development of France will have been accomplished in six years. The purposes for which power was developed during this period were: Industrial uses, 308,000 hp.; electrochemistry, 216,000; electrometallurgy, 326,000.

When completed these plants will represent a capital investment of $127,766,000. Prior to 1915, $154,400,000 was invested in power plants in France, making a total investment to date of $282,166,000.

Condition of the Scottish Shale Oil Industry

The reports of the Scottish shale oil concerns, issued in the early months of 1919, showed very satisfactory returns, in one instance the dividend being as high as 40 per cent, including income tax, but later developments, due to labor difficulties and a general increase in operating expenses, placed the industry in a much less favorable position. At meetings of stockholders and directors held later in the year, gloomy forecasts as to the future of the industry were made, and a severe drop took place in all the shares. Negotiations were entered into by the Scotch companies with the Anglo-Persian Oil Co., with the result that a new company was formed, called the Scottish Oils, Ltd., which took over the ordinary shares of the Scotch companies. It is stated that the new development is likely to lead to a largely increased quantity of crude oil being dealt with in the Scottish refineries, for, while the refining of shale oil will continue, it is expected that imported crude oil will be used to supplement the shale oil supplies, thus keeping the refineries fully employed. It is probable that this arrangement will improve the situation of the shale oil companies, although the actual production of shale oil may decrease.

Nitrogen Fixation by the Haber Method

Theoretical Consideration of the Process—Preparation of Gases for Catalysis—Design of Apparatus—Existing Plants—United States Nitrate Plant No. 1—Cost and Difficulties in Operation—Future Development by the Government—Conclusion as Compared With Cyanamide Process

By CHESTER H. JONES

IN REFERRING to the four most important processes discussed in connection with nitrogen fixation—namely, the arc process, the Haber process, the cyanamide process and byproduct ammonia output—it is essential that the characteristic difference of each be noted as distinguishing it from others. Confusion may be avoided by remembering that the arc process delivers nitric acid or some form of nitrate as the primary stable compound, while the three others produce ammonia in the form of a gas.

The Haber process is often called the synthetic process, but is no more truly synthetic than the arc or the cyanamide method. The arc and Haber operations involve the handling of gases and liquids, while the cyanamide deals principally with solids up to the final stage. In the manufacture of byproduct coke and in gas works as well, ammonia is given off as an incidental gas. It is usually absorbed in sulphuric acid to form ammonium sulphate, and this can also be accomplished with the ammonia from either the cyanamide or the Haber process.

Haber Method

The procedure consists in forming synthetic ammonia by passing a mixture of hydrogen and nitrogen, previously purified, over a suitable catalyst under a pressure of 3,000 lb. per sq.in. (20.7 kg. per sq.cm.) at a temperature of 550 deg. C. The composition of the catalyst compound which is commercially successful is a secret known to Germany alone, although it is thought to be a modified iron composition in spongy form.

About 70,000 cu.ft. of hydrogen and 23,500 cu.ft. of nitrogen (1,960 and 458 cu.m. respectively) rated under normal temperature and pressure is required theoretically for every metric ton of ammonia produced. Depending upon the condition of the catalyst and the purity of the gases only a relatively small amount of the total volume passing through the catalyzer bombs or containers is actually converted into ammonia, and it is therefore necessary to separate the latter from the system by refrigeration, returning the excess uncombined gases for recirculation.

FIG. 1. WATER GAS PLANT FOR PRODUCING THE TWO REQUISITE GASES AT U.S.N.P. NO. 1

Production of Gases

While hydrogen may be secured from any one of several sources, such as the electrolytic cell, with its consequent byproduction of oxygen; the steam-iron processes used in connection with the fat hardening industry; or the Linde water-gas method as first attempted and subsequently abandoned, the most promising source of both hydrogen and nitrogen is the water-gas plant well known in the commercial gas industry. In recent developments of the process additional nitrogen is introduced near the end of the operation, as will be later described.

Blue Water-Gas

An ordinary water-gas plant is installed in which steam is blown into a bed of incandescent coal, where it is dissociated into hydrogen and oxygen, the latter immediately reacting with the carbon to produce carbon monoxide. Some carbon dioxide is also formed, the summation of reactions being as follows:

$$N_2 + 3H_2O + 2C = 3H_2 + CO + CO_2 + N_2$$

The nitrogen enters in the form of air and passes into the gas holders with the other gases. It is readily noted that the right hand side of this equation contains the necessary hydrogen and nitrogen to produe ammonia and that further it will be required to remove the carbon monoxide and dioxide before the proper combination can be effected.

Preparation for Catalysis

The blue water-gas is drawn from the gas holders into large compressors, where it is raised to 200 atmospheres pressure and passed into mains leading to the first preheater. It then enters the CO_2 catalyzers, where all the carbon monoxide is converted to carbon dioxide through combination with the oxygen, which entered with the original air, but is not shown in the equation above. The catalyst employed is probably an activated ferric oxide. Some chromium oxide may be present.

The mixed gases coming from these catalyzers, still under high pressure, are carried on to washing towers, where the carbon dioxide is removed by water. Fifty per cent of the energy required for pumping water into these towers is recovered from the high pressure exhaust water by means of a Pelton wheel. It has recently been proposed that the carbon dioxide in this wash water be employed in making soda ash, or for other manufacturing purposes.

The traces of carbon monoxide still remaining in the hydrogen nitrogen mixture are then removed in a puri-

fier containing ammoniacal cuprous chloride solution of such strength as not to attack the iron container. There are said to be other purifiers in series with this one for the removal of oxygen and perhaps some other impurities which may be harmful to the ammonia catalyst, but definite information is not available for publication at this time.

The completely purified gases, and they must be very pure indeed, finally enter drying towers for the removal of all the moisture. These towers employ calcium chloride as a drying agent in at least one plant. Thence they are conducted to a preheater, where the temperature is raised to 550 deg. C., and subsequently into the ammonia catalyzer. The reaction is shown by the equation

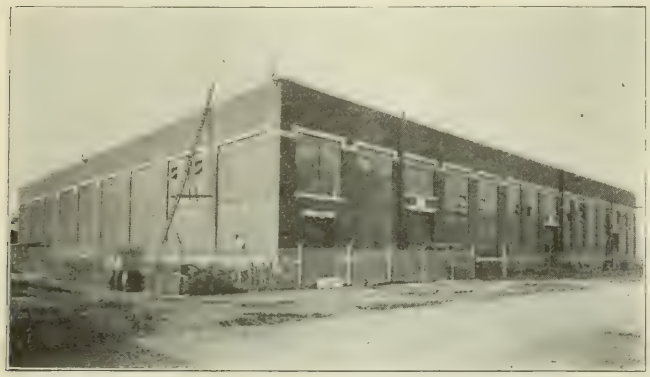

FIG. 2. AMMONIA PROCESS BUILDING, WHERE GASES ARE SYNTHESIZED TO AMMONIA. U.S.N.P. NO. 1

$$3H_2 + N_2 = 2NH_3$$

The ammonia is separated from the uncombined gases in a standard refrigeration system with liquefying arrangement. The residual nitrogen and hydrogen are returned to the system, as previously mentioned. The liquid ammonia is permitted to evaporate and pass into the mains or standard type of gas holders.

Mechanical Design of Apparatus

Because of the high working pressures all apparatus, including catalyzers, preheaters, washing towers, piping and valves, must be of extremely heavy design. The washing towers, for example, are large steel forgings resembling in appearance the huge naval guns. They are made from chrome-vanadium steel and have walls several inches in thickness.

The bombs containing the ammonia catalyst are built for resistance to pressure, lined with a refractory to resist the high temperature and with additional provision against leakage of hydrogen to the atmosphere with consequent explosion. The latter feature is covered in the most recent design by surrounding the container with an atmosphere of pure nitrogen under pressure slightly in excess of that within, so that in case of any leak the inert gas will flow inward and little harm result. The nitrogen is supplied for this purpose from standard Claude or Linde liquid air plants.

Those who have seen the immense installations at Oppau and Merseburg in Germany speak in most complimentary terms of the marvelous mechanical achievements entering into the makeup of these plants. One observer stated it made him feel proud of the human race to view the work even if it had been carried on by an enemy people.

The General Chemical Co. process, also known as the modified Haber or the De Jahn process, after the inventor, is essentially as described in the foregoing paragraphs except the plant is operated under a pressure of 100 atmospheres and a different catalyst is employed in the ammonia plant. The mechanical features are also of a considerably lighter design. The German plants differ in that nitrogen is secured from liquid air apparatus, only hydrogen being used from the water-gas plant.

Existing Plants

There are only three plants using the Haber method in the world today, with a fourth under construction. Only two of these have ever operated successfully. The first is located at Oppau, Germany, with a rated capacity of 400 tons of ammonia per day; the second at Merseburg, rated at 700 tons per day. U. S. Nitrate Plant No. 1, Sheffield, Ala., is designed to produce fifteen tons per day, but has never passed the experimental stage of operation. The Atmospheric Nitrogen Corporation, capitalized for $5,000,000, with a directorate made up of General Chemical Co. and Solvay Process Co. officials, is erecting a plant employing the De Jahn process near Syracuse, N. Y. Ten units are being installed. The total capacity of this plant has not been made public, but it will probably not exceed sixty tons of ammonia per day.

Experimental work was carried forward both in this country and abroad during the war, all on a laboratory scale except the Government plant mentioned above. It is evident that the commercial organizations learned enough through the research at this plant to risk considerable capital in the new venture.

Development in Germany

Although many difficulties were encountered in constructing a commercial catalyst unit capable of withstanding the necessary pressure and temperature, the process was eventually brought to a commercial stage in Germany in 1913. It has been said that the government would never have entered the war without the prospect of explosive output from this process. The production of ammonia from these plants was as follows:

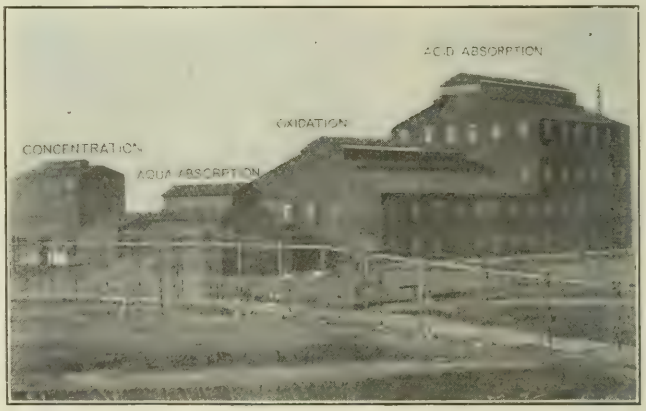

FIG. 3. NITRIC ACID PLANT U.S.N.P. NO. 1. THE AMMONIA MAY BE EITHER ABSORBED IN WATER TO PRODUCE AQUA OR OXIDIZED OVER PLATINUM GAUZES AND SUBSEQUENTLY ABSORBED IN WATER TO PRODUCE NITRIC ACID

	Tons
1913	7,500
1914	15,000
1915	37,500
1916	75,000
1917	125,000
1918	265,000

In terms of ammonium sulphate these quantities are multiplied by a factor of 5.6, giving a production of 1,960,000 tons $(NH_4)_2SO_4$ for 1918.

The Germans have jealously guarded the details of the process and very little real information was brought to this country by our investigators during the war. The samples of catalyst supposedly coming from Germany were never large enough to analyze. Even since the armistice no commercial details have been made available to the Government.

Other Developments

The Nitrogen Products Committee of the British Government has issued a final report which is now a matter of public record. This publication, Cmd. 482, contains a wealth of information relating to the process as investigated by the Ministry for Munitions of War. The committee experienced difficulty in estimating the degree of reliability to be accorded to the evidence on costs that had been obtained, but the results provided assistance in the formation of tentative conclusions.

In view of the claims that the process was capable of producing ammonia and ammonium sulphate at a low cost, and that the power requirements per unit of nitrogen were much smaller than any other process of fixation, information was collected from every available source. The economics of the process are principally governed by (*a*) the cost of the gases, particularly that of hydrogen of the requisite degree of purity, and (*b*) the capital cost of the catalyst or high-pressure section of the plant with the cost of its maintenance.

Because of the doubtful value of the figures and the difficulty of translating them to apply to manufacturing conditions in the United States they are omitted from this article. Modifications recently made in design of plants also alter the manufacturing costs.

Among other recommendations, however, the committee advised that "The synthetic ammonia process should be established forthwith on a commercial unit scale and extended as rapidly as possible, as a post-war measure, up to a minimum manufacturing scale of 10,000 tons of ammonia (equivalent to 40,000 tons of ammonium sulphate) per annum." The United States will not be up to this figure if the plant at Sheffield is operated under the bill now before Congress.

France and Italy have done practically nothing with the Haber process, relying for production on the cyanamide plants.

Construction of U. S. Nitrate Plant No. 1

Official report of the Nitrate Supply Committee and some of the circumstances following its presentation are best described in a document submitted to the Graham House committee by Colonel J. W. Joyes in his testimony, Jan. 3, 1920, as follows:

> With the object of securing an opinion, based upon a comprehensive view of all the facts collected by the several agencies, the Secretary of War appointed the following Committee on Nitrate Supply:
>
> Brigadier General William Crozier, Chief of Ordnance, United States Army, War Department; Rear Admiral Ralph Earle, Chief of Bureau of Ordnance, United States Army, War Department; Brigadier General William M. Black, Chief of Engineers, United States Army, War Department; F. W. Brown, Bureau of Soils, Department of Agriculture; Dr. Leo H. Baekeland, Yonkers, N. Y.; Gano Dunn, 43 Exchange Pl., New York; Dr. Charles H. Herty, 35 East Forty-first St., New York; Dr. William F. Hillebrand, Bureau of Standards, Department of Commerce; Dr. Arthur A. Noyes, Institute of Technology, Boston, Mass.; Dr. Charles L. Parsons, Bureau of Mines, Interior Department; Dr. Willis R. Whitney, Schenectady, N. Y.
>
> This committee gave careful consideration to all the information available, and duly weighed the several purposes stated by the language of the act, recommending the following action:
>
> I. That the Government negotiate with the General Chemical Co. for the right to use its synthetic ammonia processes.
>
> II. That contingent upon satisfactory result of such negotiations, there be set aside from the $20,000,000 appropriated, such sum, estimated as about $5,000,000, as should be necessary to build a plant to produce by that process about 60,000 lb. of ammonia per 24 hr. day; location, southwest Virginia preferably.
>
> III. That out of the same appropriation $600,000, or as much more as needed, be set aside for building a plant for producing by oxidation of ammonia about the equivalent of 24,000 lb. of 100 per cent nitric acid per 24-hr. day.
>
> IV. That the War Department proceed at the earliest practical date with the construction of the oxidation plant and contingent upon satisfactory arrangements with the General Chemical Co. with the construction of the synthetic ammonia plant also.
>
> V. That the Government negotiate with the Nitrogen Products Co. with the view to a contract for the right to use that company's patents and proceed with experimentation looking toward the industrial development of the Bucher process for production of ammonia through cyanide; and that contingent upon satisfactory arrangements as above a sum not over $200,000 be allotted out of the nitrate supply appropriation.

FIG. 4. ONE OF TWO NITRATE HOUSES IN WHICH AMMONIUM NITRATE LIQUOR IS CRYSTALLIZED FOR THE MARKET. THIS LIQUOR HAS BEEN PREVIOUSLY MADE AT THE NITRIC ACID PLANT BY BUBBLING AMMONIA GAS THROUGH NITRIC ACID SOLUTION. U.S.N.P. NO. 1

> VI. That out of the $20,000,000 nitrate supply appropriation $100,000 be allotted to active investigation of processes for the industrial production of nitrogen compounds, useful in the manufacture of explosives or fertilizers—this under supervision of the War Department.
>
> VII. That in order to increase the production of ammonia and toluol the Government promote the installation of byproduct coke ovens by directing priority in production and transportation of materials and parts.
>
> VIII. That the decision as to more extensive installation of nitrogen fixation processes and water-power development in connection with them be postponed until the plants above recommended are in operation or until further need arises.
>
> IX. That while the preceding recommendations include all the measures that can now judiciously be taken for the fixation of ammonia, it is the opinion of the committee that the immediate accumulation and the permanent maintenance of an ample reserve not less than 500,000 tons of Chilean saltpeter is the measure most urgently necessary.
>
> The foregoing report having met with general approval, the Secretary of War has directed the Chief of Ordnance of the Army to proceed to carry out the first six of the recommendations of the Nitrate Supply Committee and has announced that for the present the consideration of development of large water-power installations which had been begun by the interdepartmental

board (Secretaries Baker, Lane, and Houston), appointed by the President, would be suspended.

The outstanding feature of this program for action is the construction of the synthetic ammonia plant, using the General Chemical Co.'s process, which was largely developed by their engineer, Frederick de Jahn. As has been indicated, this process has already had trial upon a sufficient scale to demonstrate the practicability and to indicate as most probable its ability to produce ammonia at a very favorable price. In fact, in the search of the Nitrate Supply Committee for the best, cheapest, and most available means for the production of nitrates and other products that would be of use in the manufacture of munitions and in the manufacture of fertilizers this process appeared to give more promise of affording relief from dependence upon foreign nitrates for the defense of the country and more promise of a reduction in the cost of the nitrogenous constituent of fertilizer than others. Furthermore, this process is one which can be put into operation in a much less time than would be required to develop such a large water power as would be needed for other prominent processes available.

Value of Haber Process

The Bureau of Mines reported to the Ordnance Department, U. S. Army, on Jan. 27, 1917, the following observations in regard to the Haber method:

> The technical control of the Haber process is of such great importance and requires so high a degree of training and skill that it is reported if the Badische people were to lose their present technical staff of experts, familiar with the process, many months would be required to train another staff capable of applying the process in practice.
>
> The Haber process is not at present in use outside of Germany on account of the lack of detailed information regarding plant construction and operation, and also owing to the very large royalty demanded by the Badische Co. for its use by other concerns. It is, however, more than probable that the Badische Co. will itself install and develop the process outside of Germany when the war is ended.
>
> Trustworthy information regarding the costs of production of ammonia by the Haber process indicates that pure anhydrous ammonia can be produced in liquid condition for a cost slightly less than 4c. per lb. It is improbable that any arrangement could be made for the United States Government to use the Haber process pending the conclusion of the European war. It is probable that when the war is ended the Haber process will be installed or will be available for installation in the United States. It is the cheapest process for the production of synthetic ammonia. It is independent of cheap power, the power being a small fraction of its cost. If desirable, it could be readily installed in moderate-sized units in connection with ammonia oxidizing plants at any munitions plant.

Advantages

1. Cheap ammonia.
2. Ammonia in water-free liquid condition ready for oxidation without purification.
3. Availability of raw material (air and coal).
4. Possibility of erecting comparatively small plants wherever needed.
5. Easy availability of product for transportation and for fertilizer.

Disadvantages

1. Inability to procure technical details, use of method, and trained technical force without the assistance of the Badische Co., except as the result of many months and probably years of experimentation. This is largely owing to the difficult engineering problems involved in the use of pressure as high as 150 atmospheres and temperatures of 500 to 600 deg. C.
2. High repair and renewal costs.
3. Undoubtedly high royalty that would be demanded if the Government were to install and operate this process itself. Inability to come to terms with the Badische Co. as to the use of its patents is reported to have been the sole reason for the non-adoption of this method by two large American corporations and one Norwegian corporation.
4. Patents and processes controlled in America by one corporation.

It is presumed that the Bureau of Mines report was prepared by Dr. Parsons. His prediction as outlined with regard to post-war installation in the United States is being fulfilled in the erection of the new plant at Syracuse, N. Y.

Estimated Cost of Plant No. 1

The sum of $3,000,000 estimated by the Nitrate Committee as being necessary for the erection of the process plant at Sheffield, Ala., was not in any sense a construction estimate, but based on figures submitted by the General Chemical Co. They were made by employing the best information available in the United States at the time.

Arrangements were made for the Government to take over the orders which the General Chemical Co. had placed in the market for apparatus to be used in a private plant the company had previously planned. Thus both time and money were saved.

Actual Total Cost

The final value of the property known as U.S.N.P. No. 1 is recorded as $12,689,677, including overhead charges, such as design, administration, freight, insurance, distribution system, roads, walks, etc. The ammonia plant cost about $5,592,000, the acid plant about $2,184,000, the ammonium nitrate plant $386,000, the power plant $1,552,000, land and plant accessory buildings about $1,406,000 and the permanent village for housing employees about $1,852,000.

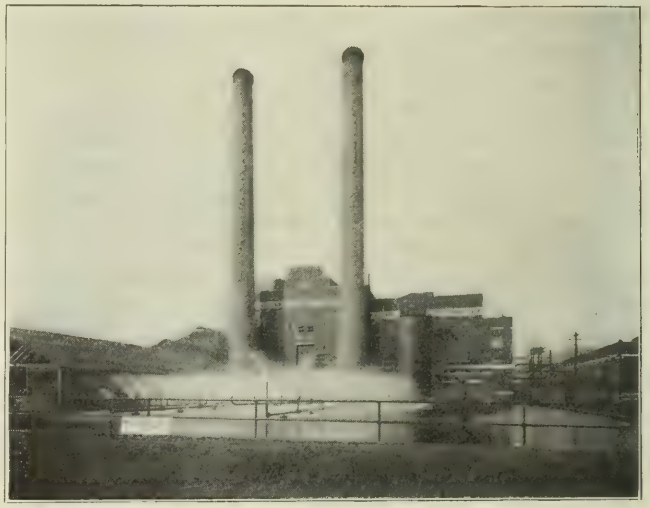

FIG. 5. POWER HOUSE AND COOLING POND. U.S.N.P. NO. 1

The process is practically erected complete, the exception being two units in the ammonia plant, which will await slight changes in design. The work has been discontinued for nearly a year, with only a small force for guard duty and maintenance work located on the property at the present time.

Operation Troubles

In describing the difficulties encountered during the operation period Colonel Joyes said:

> The process depends upon the chemical reactions, which are very delicate. . . . Conditions have to be just about right, and to stimulate it so that the proper portion of the gases are synthesized a catalyst is used, and a catalyst in general is very subject to being poisoned and rendered inoperative by any foreign

FIG. 6. MACHINE SHOP, U.S.N.P. NO. 1, EQUIPPED TO HANDLE REPAIRS ON HEAVY AMMONIA PLANT APPARATUS

substance that may be in the gases. The General Chemical Co. had a catalyst they developed and that had given very good results in the laboratory tests. They had made the active material on a small scale, without much trouble, but when they commenced to produce it in quantities for use as a catalyst at this Government plant considerable difficulty was encountered.

Furthermore when the catalyst was put in the vessel at the plant and operation started, it was found to be very sensitive indeed toward all unfavorable conditions such as a slight amount of moisture or impurities in the gases.

We had trouble also with the apparatus. Some of the valves failed to hold the gases at high pressure. Some of the vessels exploded, especially one heater where the gases had to be brought up to an elevated temperature. Presumably the pipes in the heater were attacked by the gases, and we had a pretty bad explosion; we had a fire from it and so on. . . . The metal is eaten away, and we have samples of tubes which were exposed under those conditions and completely eaten away in a very short time.

The longest period of continuous operation of the ammonia plant was seventy-two hours. The total amount of ammonia produced, including all experimental runs, did not exceed thirty-four tons. The total amount of ammonium nitrate manufactured, including that produced from ammonia liquor shipped from coke plants, did not exceed eighty-five tons.

Future Prospect for Operation of Plant No. 1.

The successful operation of the Haber process at the Government plant is entirely dependent upon the action of Congress on the bills now pending for appropriations to carry on the necessary research work, both at the American University laboratories and at the plant in Sheffield, Ala. Funds are now available for continuation of the laboratory work until June, 1921. This research is very essential in order to determine the best catalytic material for the synthesis of ammonia, and the laboratory organization is now very actively engaged with extensive equipment, as will be described in a later article. The plant must be operated in conjunction with the research to perfect the process for commercial operation.

Henry Wigglesworth of the General Chemical Co. estimates that with the expenditure of less than a quarter of a million dollars for making changes and tuning up, Plant No. 1 can be made to work satisfactorily in producing ammonia. Whether this estimate is low or not makes little difference because the Ordnance will have sufficient funds for vigorous prosecution of the work if the bills providing for the establishing of a Government nitrogen corporation are passed in Congress, according to estimates of George Roberts.

Conclusion

Aside from the opinions of the scientific investigators who have become enthusiastic over the possibilities of the Haber method, it is still considered by the more conservative technical men to be the coming process for nitrogen fixation, because of the lower cost of manufacture combined with the purity of product. This does not mean that the other methods of fixation are obsolete, but rather that if the industry is to be developed to keep pace with other nations we must look for the research in this process to be carried on by the Government.

The cyanamide process is the only practical and commercial method established in the United States today for the direct fixation of atmospheric nitrogen, and this fact should not be clouded by any plans as to the future. It is even possible that it may never be entirely displaced by another method. This may become more evident as new derivatives are discovered in making cyanogen compounds from cyanamide.

The Government officials will doubtless adopt a well-balanced policy with consideration for both present production and future development.

Final report of Nitrogen Products Committee, British Government.

Testimony before the Graham House committee, U. S. Congress.

Interviews with U. S. scientists and operators.

New National Hydraulic Laboratory Proposed in Buenos Aires

According to Trade Commissioner Brady the Argentine National University at La Plata has petitioned for a hydraulic laboratory to be used in experimental work by the engineering students. Already the Minister of Public Works has reported favorably on the project and has asked that a piece of land 975 ft. x 1,625 ft., in the Buenos Aires port between the East Canal and the Port Railway, be allotted for the construction of the laboratory. Final approval of the project will rest with the Argentine Congress at its next session in May. Efforts of American manufacturers in the past to introduce laboratory apparatus and machinery into the colleges of Argentina have not equaled those of their European competitors. Now an opportunity is offered them through the construction of this national hydraulic laboratory to place their equipment before prospective Argentine engineers.

Unique British Advertising Plan

The Federation of British Industries has devised a unique scheme for advertising home manufactures in all parts of the world. A new steamship, to be called the Federation, is to be constructed by some of the leading firms of the country as an exhibit of British marine engineering. The cargo of the ship will consist of various articles of British manufacture. Representatives of the firms interested will make the voyage for the purpose of showing their goods and interviewing foreign buyers.

Legal Notes

By Wellington Gustin

Conveyance of Property Subject to Mortgage

A victory was recently won by the Virginia Zinc & Chemical Corporation, Ltd., and others, in the suit instituted against them in the Virginia courts by C. B. Van Nostrand & Co. and others, when the Supreme Court of Appeals of Virginia affirmed the decree rendered in the lower court fixing liens and priorities as to claims against the forty acres of land upon which is located a manufacturing plant, situated near Bristol, Va., the property of John T. Williams, and postponing the judgment liens of plaintiffs to those of defendants and decreeing a sale of the property to discharge the liens.

It appears that John T. Williams executed a deed of trust in 1912 to the Windsor Trust Co., conveying the above property to secure seventy-five $1,000 notes, bearing 6 per cent interest, payable semi-annually, for the purpose of negotiation to realize money to discharge his liabilities. At this time there was a prior mortgage on the property to secure a note for $8,500. Both of these deeds were duly admitted to record. On Dec. 31, 1913, by agreement the parties changed the date of the seventy-five notes to Oct. 1, 1913, payable one year after date. This agreement was recorded Jan. 31, 1918.

To relieve his pressing indebtedness, John T. Williams, acting through his son John T. Williams, Jr., induced Mrs. Nellie B. Crouch of St. Louis, Mo., mother-in-law of the son, to purchase his note for $33,000, secured by the seventy-five $1,000 notes, for which she paid $30,000 in cash. Through her husband, Mrs. Crouch became the owner of the note of $8,500. From the cash obtained Williams paid off the $8,500 note, the balance being applied to payment of his other liens and debts. In 1914 Mrs. Crouch purchased an additional note for $5,500 and another for $500, and in 1915 she paid delinquent taxes and insurance premiums on the property for Williams, aggregating $1,417.42, for which he made his note. The total notes of Williams thus held by Mrs. Crouch amounted to $40,417.42, all secured by the same issue of notes as collateral security.

In 1914 John T. Williams and wife executed a deed transferring and conveying the forty acres of land and manufacturing plants to the Virginia Zinc & Chemical Corporation, subject expressly to the deed of trust securing the seventy-five $1,000 notes.

Sale of Property and Contentions of Plaintiffs

The notes given to Mrs. Crouch contained a provision empowering the holder to confess judgment for the maker for the amount due thereon "and to sell or cause to be sold any or all of said collaterals, or any substitutes therefor, or additions thereto, at public sale upon such notes, at such place, and on such terms as the holder of said notes," etc., may deem proper, applying the proceeds to the discharge of the liability due the holder. The holder under any such sale was permitted to become the purchaser without any right of redemption. After default on the notes they were sold at St. Louis, after due notice and publication, and Mrs. Crouch became the purchaser at the price of $10,000. Deducting the expense of the sale, the balance was entered as a credit on the demands due her of $33,000.

John T. Williams, Jr., as trustee of the real property, advertised it for sale under the deed of trust. C. B. Van Nostrand & Co., Packard & Co. and others having judgments against the Virginia Zinc & Chemical Corporation, recovered in the Circuit Court, asked for an injunction preventing the sale as advertised by Williams, Jr., and for an accounting of the property, the liens thereon with their priorities and the sale of the property to satisfy these liens. The court ordered an accounting and fixed the liens and priorities, postponing the judgment liens of plaintiffs to the trust deeds and liens of Mrs. Crouch and the Virginia Zinc & Chemical Corporation. From this decree the plaintiffs appealed, contending (1) that the deed conveying the property in question to the Virginia Zinc & Chemical Corporation vested the title thereto in the chemical company, which could not be affected by the subsequent recording, in 1918, of the agreement of Dec. 31, 1913; and (2) that this agreement of Dec. 31, 1918, as well as the deed of trust covering the seventy-five notes, was fraudulent as to the judgment creditors of Virginia Zinc & Chemical Corporation, and should be declared null and void.

Court Answers Plaintiffs' Contentions

Answering the first contention, the Supreme Court of Appeals said there was no proof that the rights of the plaintiffs were affected by the failure to record until Jan. 31, 1918, the agreement dated Dec. 31, 1913, changing the date of the notes secured by the mortgage. It was not necessary to record this paper at all. The change of date in no way affected the debt secured. The mortgage remains a lien until the debt it was given to secure is satisfied, and is not affected by a change in the note. And, again, it was claimed that as there was no debt at the date of the execution of the seventy-five $1,000 notes, the deed of trust therefor was invalid. But the court said this claim was without merit, for in the business world nothing is more common than the execution of such securities in contemplation of a loan. As soon as a note is negotiated, the liability to take care of it arises, and the holder's right to the security attaches.

On the second contention, that the instruments were fraudulent as to judgment creditors of the corporation, these were subsequent creditors, and, having contracted their debts and recovered their judgments against the purchaser of property conveyed subject to a mortgage of record, their judgments were recovered with constructive notice of the nature and extent of their debtor's interest in the mortgaged property. Hence they cannot complain of the mortgage as being fraudulent as to them.

London Metal Prices for Twenty Years

An interesting and instructive chart has been compiled by Vivian, Younger & Bond, of London, showing the prices on the first day of each month during the past twenty years (1900 to 1919, inclusive) of spelter, standard copper, tin, soft lead without silver, standard silver, and Scotch and Cleveland iron. The chart also shows the British bank rate prevailing at various dates during the same period, and the highest and lowest prices in each year of the metals enumerated—in which very considerable fluctuations are recorded.

Scientific Control of the Filter Station—II

A Discussion on the Rate of Flow of Filtrate—Critical Pressure—Graphical Analysis of Rate and Amounts of Flow—Influence of Temperature and Density Changes—Use of Filter-Aids in Filtering Colloidal Materials*

BY ARTHUR WRIGHT, M. E.

THE maximum capacity of filtrate outflow from a filter is the goal of every ambitious operator, and some ingenious efforts have resulted in failures due to an incomplete comprehension of the underlying principles.

The attack most often pursued is to increase the filtering pressure. This is logical, for the filter medium and the cake can be considered multiple orifices, so that the law applies that the flow through an orifice is proportional to the pressure. That an increase of the pressure thus increases the quantity of filtrate is not universally true. It is practical with almost theoretical accuracy when handling solids of a crystalline or granular texture. It is true to a certain extent with every material, but with some only through a small range of pressure. Those with the smallest limits are flocculent precipitates with which a few feet increased head of gravity feed is all that will increase the flow before a contrary result is obtained.

Increased pressure is identical with increased suction when operating vacuum filters. There have been misconceptions on the difference of pressure and vacuum filtration. Much discussion has arisen over the merit of "pushing" the liquid through the filter as is the case with pressure type machines, and "drawing" it through with vacuum filters. The action here is not analogous to that of the familiar law of mechanics where a cane can be drawn along a pavement easier than it can be pushed along. The action in pressure and suction filters is identical, for the filtering force in either case is the difference of pressure on the two sides of the medium, in the one case it being the pressure due to a pump or head greater than atmospheric pressure; in the other that of the atmosphere compared to a pressure lower than atmospheric. In consequence laws pertaining to pressure filtration apply also to vacuum filters, although the range of difference in pressure is limited to 14.7 lb. per sq.in. as the theoretical maximum with the latter.

CRITICAL PRESSURE

The reason that, in practice, the law of increased pressure does not always increase the flow is found in the fact that for every material there is a pressure above which an increased flow is not obtained, but a decreased flow is had instead. This is known, in filtration parlance, as the critical pressure for that material. Confusion sometimes occurs on this point, for an operator will, after filtering at a given pressure, jump his pressure up and point to the larger stream discharging from the filtrate outlet. Unfortunately for him the flow does not last long. It is occasioned by the fact that the increased force compacts the cakes on the leaves and forces the entrained liquid out through the filter cloth. After this momentary rush, however, the rate is lower. It is difficult to estimate the critical pressure for the various materials handled in industrial filtration or even for any one material, for local conditions surrounding the precipitation of the solids or handling can widely affect its filtering characteristics. It is not, however, difficult to ascertain the critical pressure in any plant if experimental runs be made with periodic readings of the flow filtrate taken and all the other factors as affect the rate of flow maintained constant. With these readings it is simple arithmetic to figure the rate of flow per unit area for the successive periods at which the readings were taken. A graph then can be plotted, the abscissæ being the time of filtration and the ordinates the rate of flow. It is interesting to find how completely experimental observation is corroborated by such a plot.

GRAPHICAL ANALYSIS OF RATES OF FLOW

Representative curves are shown in Fig. 1. *AB* is that of a liquor containing crystalline solids or materials of similar texture which are free filtering products. This is practically a straight line slowly breaking into a hyperbola, and the interpretation is that the rate of flow falls off at equal increments, each increase in thickness of cake causing a corresponding increase in the resistance to the flow. The statement that "it is a straight line" is approximate and true only when applied to the usual working limits. The line eventually bends and resolves itself into a hyperbola, slowly approaching but never reaching zero. This curve represents that of the easiest filtered materials.

The curve *CD* is typical of the vast majority of difficult materials handled. The initial flow is high, with a rapid fall until a low rate is obtained, decrease in which is small. The goal of every filter experimenter is to change the form of this graph and make it approach *AB*. *EF* will represent the fruit of such efforts and in lay language means that by a modification of the material as precipitated or by modifying the method of handling the material it is changed to a more easily filtered liquor.

To some, such a discussion may seem too academic and when incorporated as the results of a test a graph is often somewhat superfluous, but to the experimenter working out the problem it is of inestimable value. It is a big factor in maintaining a broad point of view and prevents premature satisfaction when better results are to be obtained by means of further research.

There is a considerable amount of additional information to be had from a study of these curves, such as a point of flexure indicating the economical length of cycle, computation of capacity by planimeter methods, etc., but such data are better obtained by other methods, as will be elaborated upon. The principal help from

*For Part I, see Chem. & Met. Eng., vol. 22, No. 23, 1920, p. 1111.

these graphs is in noting their general curvature or shape and comparing the curves obtained from modified operation with that of a previous run. In this respect they serve a most useful purpose, for with all factors kept constant, save a modified pressure, these graphs are indelible proof of the existence of a critical pressure and the most definite means of obtaining it.

Influence of Temperature and Density Changes

What is true of pressure being an important factor in the rate of flow is equally true of the temperature of the slurry and density of the liquid at which it is filtered. Here we have to deal not with a critical temperature or density of filtration, for with most materials practical economy dictates this before the limit which filtering efficiency requires is reached. The hotter the

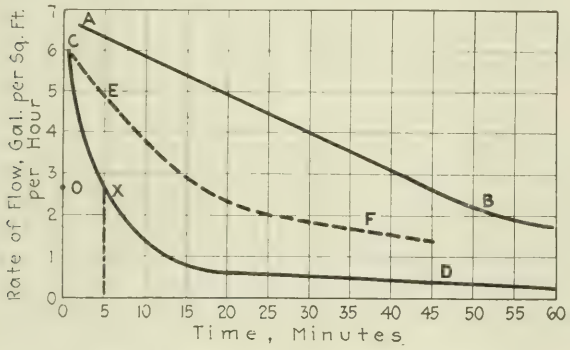

FIG. 1. RATE OF FLOW CURVES

liquid is the thinner it becomes and the better will be the rate of flow. For the proper determination of the right temperature and density the costs of heating, evaporating, and maintaining the heat must be had so as to balance the increased work of the filters. It is, however, too often unappreciated that there is a very rapid rise in the viscosity with increased density and decreased temperature as shown in Figs. 2 and 3. In Fig. 2 it is quite apparent that below *Y* a few degrees difference does not greatly affect the viscosity, but around *X* 2 or 3 degrees difference in tempearture marks a distinct difference. Such information is of course not due to filter development, but is of value to the operator and teaches him the need of a nice control of temperature and density.

The Economical Filtering Period

In practically all phases of filtration discussion the rate of flow is synonymous with cake building. It is apparent that if a dry, hard cake is desired from a plate and frame filter press the frames should be designed so that the cakes on the two sides of each frame shall join together before the rate of flow has fallen off too greatly. If the time required to build the frame solidly full is too prolonged, the cycle is bound to be uneconomical.

A further study of the curve *CD* shows us that if it were possible to work this material only for the time represented by *OX* we would be working at the economical part of its filtration. Such a scheme means, however, short filtering periods and is feasible only in those types of filters wherein automatic discharge and continuous operation are had. Here we find the fundamental principle of continuous vacuum filtration and while possibly in a sense this is not ways and means of bettering the rate of flow, it is basic in that maximum capacity is had not by a modification of the filtering characteristics of the material being handled but by a mechanical device to meet the conditions of the material "as is." This has its importance when materials are not subject to temperature or density variation and it is required only that the deposit of the solids shall have a sensible thickness and be efficiently discharged. It is true that most applications of continuous vacuum filters are on materials of a free-filtering character, but the basic idea is as explained nevertheless.

The total flow curve is often used and from it capacity is read directly. Its curvature is not as sharp as in the rate of flow curve and is consequently not quite as informative as the latter. The curve is the simple plot of time of filtering as abscissa and total flow at time of reading as ordinate as shown in Fig. 4. Too long a filtering period is cumulative in its evil effects. Washing is slower, cake hardness less and the chance of a clean cleavage of the cake from the filter cloth jeopardized. This fault of an uneconomical cycle due to the width of the frames in plate and frame presses being too large is entirely too prevalent throughout industrial filtration and is due to inadequate determination of the filtering characteristics of the material being handled.

One advantage in leaf type filters is that it is not necessary to continue the filtration until a hard cake is obtained. This means then that the filtration can be discontinued at any time without jeopardizing the dryness of the cake. It is in these filters that the operator is afforded the most opportunity to effect best results as regards maximum capacity. The point to be kept in mind is that the rate of flow is constantly decreasing and when working at the low point of the curve the outflow

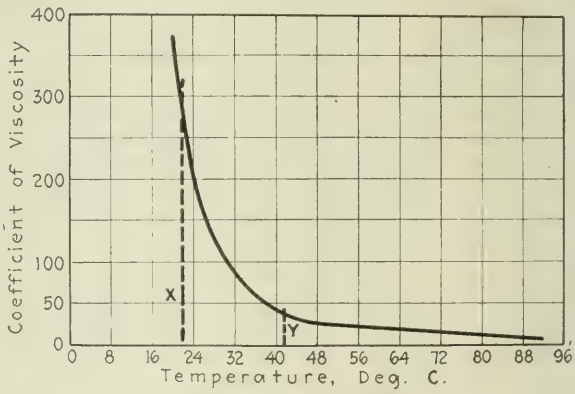

FIG. 2. TEMPERATURE VISCOSITY RELATION

is not commensurate with the time required. There will be discussed in a later paper a mathematical means of determining the economical length of cycle which gives consideration to the washing, drying and discharging periods, but it is well to have in mind the general character of the rate of flow curve.

Homogeneity of Cake Important

Oftentimes liquors have to be handled in which the solids of suspension are a mixture of coarse and fine particles. For maximum rate of flow agitation must be maintained in the filter so that the deposit both at top and bottom of filter medium is made up of the mixture of coarse, free-filtering solids and the fine, more difficult-filtering material. If classification takes place so that the lower part is coated with the coarse material

and the upper part with the fine, then tapering cakes are sure to be formed and all the evils of discharging, warped leaves, etc., will ensue. This leads to a point for further consideration, for if the liquor in the filter classifies and filtration is started, no amount of agitation from that time on is of any practical value. The solids that build up the cake are carried to their positions by their respective stream lines. When a cake becomes highly resistant to filtration so that the flow is cut down, the stream lines of the liquid are weak and can carry particles only that are easily moved. This is the case when the upper part of the leaves become coated with the finer particles of suspension. No amount of uprising current which will carry the coarse particles upward can aid the deposition of the heavier particles at the top of the leaves. The stream lines are at right angles to the filter surface and strong stream lines are necessary if the velocity is to be sufficient to deposit the coarse particles on the cake surface. The above, therefore, emphasizes the fact that the initial deposit on the filter medium is vital if the best rate of flow is to be obtained. There is a corollary to the last statement; that the initial pressure should not be excessive. The reasoning on this is that too high an initial pressure compacts the first deposit so as to make it too resistant and lowers the capacity. Fortunately, low initial pressure is common practice, for if the pump is not too large the initial outflow of filtrate will approximate the throw of the pump and the pressure will rise slowly. It is only when an excessively large pump feeds the filter that the rise in pressure is rapid and this trouble is encountered.

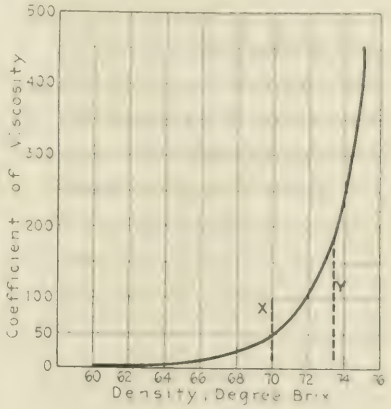

FIG. 3. DENSITY VISCOSITY RELATION

The initial resistance of the filtering fabric, drainage member, etc., should be as low as possible. This fact is apparent but has been over-emphasized in some designs of filters in which excessive drainage has been provided. It must be remembered that the filtrate issues through the fabric in drops, the accumulation of which produces the filtrate flow. The drainage does not have to be very great to meet this requirement, however. In the matter of choice of filter medium, more attention is required. The demand is for one of low resistance to the passage of the liquid through it and if mechanical wear calls for a heavy cloth, then one of open weave is required. If too dense a cloth is used, the velocity of the initial stream lines causes the finer particles of suspension to be forced into the weave of the cloth and to imbed themselves so as to cut off the porosity. With coarser weaves of filter cloth these fine particles pass through the interstices and issue from the filter as cloudy filtrate which must be refiltered. This is far better than having the filter cloth clogged so that it decreases the flow and cannot be effectively cleaned on discharging.

It is quite evident that the filter cloth must be retained in a free-filtering condition if recurring runs are to show the same capacity as the first run. It is idle to point out that thorough discharge of the cakes from the cloth is required for maintaining high rate of flow, but it is a point that experimenters are often too quick to assume when dealing with a new material. Inspection of the surface of the cloth is not an infallible means of determining that the cloth is clean. The rate of flow on succeeding runs is the only safe way.

Steadily Increasing Pressure Desirable

It is becoming better recognized that a constant or steadily increasing pressure is the most desirable for obtaining the best rate of flow. Fluctuations in pressure produce an effect similar to that of tamping wet ground. The cakes are made denser and more resistant by this action. The interval in which the pressure falls is one of inefficient working, for the resistance produced by the high pressure is too great for the lower pressure rapidly to force the liquid through. This point is one of the favorable factors in the use of montejus and pneumatic eggs, gravity feed and vacuum receivers, etc. Centrifugal pumps with rotors easily accessible and with sufficient clearance to allow the pumping of coarse and gritty materials are admirable in that the pressure is in reverse proportion to the amount of filtrate flowing. This type of pump is not best when handling flocculated material, for as soon as the outflow is less than the throw of the pump the rotor has a churning action and breaks up the flocculent precipitate. Every chemist knows how much harder it is to filter such precipitates after agitating and stirring them so as to break up the agglomerated particles than when handling the material with the flocculent condition preserved. By reason of the points above outlined positive discharge rotary pumps are gaining an increased use and have characteristics well suited to filter press work.

Colloidal material or solids so fine as to approximate colloidal conditions are most difficult to handle with any degree of satisfaction or economy. They are difficult to clarify unless an auxiliary filter medium be employed and form so compact a deposit as to be almost impenetrable. Fortunately, in the majority of cases these solids are waste products and can be coagulated or will allow of the introduction of a filter-aid. The usual method of coagulation is by the production of a flocculent precipitate by chemical reactions. Enough attention to this point seems to be lacking, for too often the goal seems to be to add enough reagents to be able to note a sparkling liquor between the separate flocculent particles. It does not seem to be appreciated that an excess precipitate adds to the solids of suspension which are of themselves difficult to filter in pressure filters.

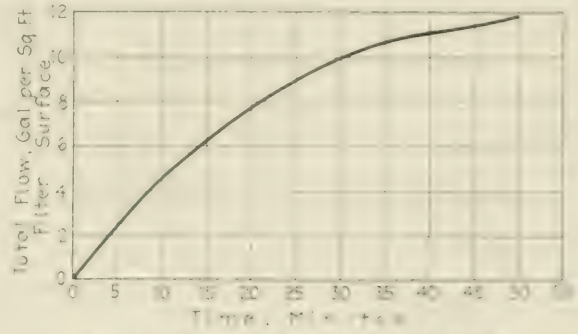

FIG. 4. TYPE CURVE OF TOTAL FLOW

It must not be inferred that the agglomeration of the

particles of suspension does not aid in pressure filtration, although this theory is sometimes advanced. There is no question that flocculation is the best means of obtaining this agglomeration of the colloidal material, but the demand is satisfied when the quantity of reagents produces no excess precipitate. This, of course, has not the same importance when only decantation methods of clarification are employed.

Use of Filter-Aids in Filtering Colloidal Materials

There is a new theory for the clarification of contrary liquors that is demanding more attention and deservedly so. If there is added to the liquor before its filtration a quantity of inert free-filtering material, it is obvious that the deposit on the filter cloth is a mixture of the free-filtering solids and the contrary precipitates. The former build up so as to preserve the porosity to a greater extent than do the latter and consequently admit of a greater flow of filtrate. The material so added is known as a filter-aid and must conform to the three specifications of being (1) inert to the liquor, (2) of a free-filtering character, and (3) of such a specific gravity that it can be handled in the filters without settling or floating.

The filter-aid is added with the idea of decreasing the resistance of the solids deposited and making the liquor free-filtering, similar to that which carries crystalline or granular solids of suspension. It has been demonstrated that only a small percentage is necessary to effect marked results, but true filtering efficiency dictates the use of quantities in excess of that generally added. It is worthy of note that when good capacity flow is obtained from a filter, a corresponding increase in the volume of the cake is obtained. The greater the bulk of the cake, the better its discharge and the filter-aid therefore simultaneously affects not only the rate of flow but the equally important factor, efficient discharge.

It would seem that the combination of the flocculating idea and the filter-aid principle ought to have possibilities. It has. The idea, however, must not be to add the filter-aid as an aid to the filtration of a liquor the solids of which have been agglomerated, for to do so only partly solves the problem. In plant practice but few instances will be found where a flocculent precipitate will not be broken up by the time the liquor enters the filters. The answer is to use the filter-aid to strengthen the structure of the flocculent precipitate by adding it to one of the defecants before its addition to the liquor. This will often require diluting the defecant, and if the water required for this is objectionable on the score of increased evaporation, no objection can be found to substituting clarified effluent for the water.

To thicken the liquor by decantation methods so as to concentrate the solids makes for increased duty of the filter. This is universally true as regards its capacity in cake discharged, although there are instances where the rate of flow is also increased. The latter as explained in that classification is minimized and the granular particles deposit along with the fine so to preserve the porosity to a greater extent. Continuous filters often are applicable on liquors that have been thickened where they are impractical prior to decantation, and there are numerous instances where this has proved the economical means of handling this material.

(Part III, dealing with Washing and Drying, will be published in a subsequent issue.)

Maple-Products Industry of Quebec Province

Official reports show that the maple-products industry in the Province of Quebec has grown markedly during recent years, its development being mainly attributed to the scarcity and increased price of beet and cane sugar. While sugar maples are found chiefly in the central and western sections of the province, the industry has to some extent developed also in the Gaspe Peninsula, the counties of Bonaventure and Gaspe showing in 1919 an output of 59,135 lb. of sugar and 3,101 gal. of sirup, as compared with an output in 1911 of 11,870 lb. of sugar and 512 gal. of sirup. No figures as to quantities are available for the county of Matane, but the products in the three counties of 1919 were valued at $20,665.

The output in the province as a whole in 1919 amounted to 12,353,667 lb. of sugar and 1,470,275 gal. of sirup, of an estimated value of $6,396,535, as compared with the 1911 output of 9,989,443 lb. of sugar and 1,005,330 gal. of sirup, of an estimated value of $1,680,393. Maple sugar ten years ago sold for 7c. to 8c. a lb. and in 1918 at an average price of 15c. a lb. The latter part of 1919 25c. to 30c. a lb. for sugar and from $2 to $2.50 a gal. for sirup were offered. The United States affords the best market for the product.

Private and Government Aid to Industry

An organization known as the Co-operative Society of Pure Maple Sugar and Sirup Makers, organized some years ago, has secured as members thousands of farmers interested in this industry. Its objects are to distribute information among its members as to the best methods for obtaining the highest quality of products and to prevent their adulteration. Through the efforts of this association a Federal act was passed prohibiting adulteration of maple sugar and sirup, and it was also responsible for the establishment of sugar-making schools, and for exhibitions and competitions in Canadian maple products.

The development of the industry has been further stimulated by the provincial Department of Agriculture through demonstrations in sugar making in various parts of the province given by skilled instructors.

The province has three sugar-making schools located at La Minerve, Beauceville and Ste. Louise. These schools provide a fifteen days' course, the Department of Agriculture paying the board of the students. Last season at these three schools 12,000 maple trees were tapped and 808 gal. of sirup, 3,775 lb. of sugar, and 100 lb. of taffy were manufactured. Thirty-three pupils followed the course, and there was an attendance of 786 visitors. The approximate period of the course, depending upon the season and location of the school, is from March 20 to the latter part of April.

Dominion Grant Toward Cost of Instruction

The 1919-20 allotment to Quebec Province from the Dominion Government, under the agricultural instruction act of Canada, for educational purposes in connection with the maple industry was $4,000.

As the farmers depend to a considerable extent upon the lumbering industry for employment in the winter, which employment terminates about the end of March, and as farm work usually does not commence until the middle of May, the maple-products industry fits in nicely with their other work.

Reinforced Lead

By Charles Baskerville and C. M. Wales

LEAD suspended in large sheets or pipes creeps or sags, so that it must be held in position. Frequent supports without (as with sulphuric acid chambers, lead ducts for sulphur gases, tank cars, etc.), lead-coated iron braces within (as in linseed oil refining kettles), or supporting retaining walls of masonry within (as with pulp digesters, petroleum refining tanks, etc.) are necessary to hold the lead in place. Vacuum pans and connections of lead must be of extra thickness ($\frac{3}{4}$ to 1 in.), hence of great weight, to prevent collapsing.

Iron and steel pipe with lead lining is extensively used, the lead protecting the iron or steel, the latter also preventing bulging of the lead when the necessary pressure is applied within to move the liquids thus transported. Lead has been flowed or burned on other metal, but each method fails in one way or another, primarily in the cost of installation.

Many of these troubles in the use of lead have been entirely overcome and others materially diminished by reinforcing lead with iron or steel wire gauze or perforated sheets, which are imbedded within the lead (U. S. pat. 1,280,908 and 1,280,909).

Fig. 1 is a perspective view of an article partially broken away. This figure shows a portion of a lead sheet which is reinforced by a ferrous gauze.

Fig. 2 is a cross-sectional view taken as on the broken line 2—2 of Fig. 1.

Fig. 3 is a perspective view of an article partially broken away. This figure shows a portion of a lead sheet which is reinforced by a perforated ferrous plate.

The elastic limit has been increased four to five fold and the tensile strength has been increased two to three fold. The variations observed were due to differences in gage of wire and mesh of gauze used. Both may be materially increased by increasing (within limits) the gage and looseness of weaving the gauze. When manufactured, the surface of the lead or lead-alloy may be somewhat rough and unnecessarily thick. Both are easily remedied by rolling, as in making sheet lead. Lateral extension of 20 per cent and elongation of 30 per cent have been obtained, the main care being against tearing the reinforcing wire gauze. Sheets 4 ft. 6 in. x 5 ft. 6 in. have been made. For obvious reasons smoothing the surface is advisable only when the reinforcing member is perforated sheet iron or steel.

FIG. 4. BENT PIECE OF REINFORCED LEAD SHEET

The reinforced sheets may be bent or shaped almost at will, as the lead does not fracture when bent (see Fig. 4). The sheets may be cut and joints are easily burned together in the same manner as ordinary sheet lead is burned (see Fig. 5).

The lead may be easily melted from an edge of a sheet and the piece shaped into pipe, the overlapping edge being then burned in position. A pipe, 8 in. in diameter, made up of reinforced lead 0.2 in. thick, collapsed at 85 lb. per sq.in. pressure.

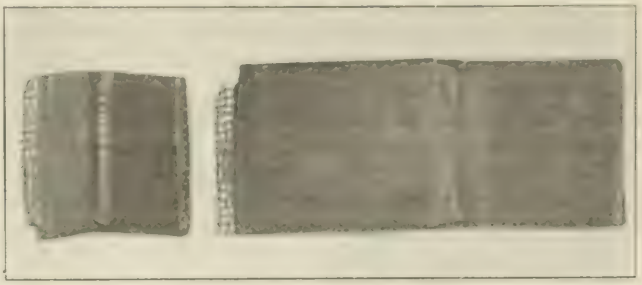

FIG. 5. JOINT PIECES OF REINFORCED LEAD SHEET

The experimental work on this material was carried out by V. A. Belcher.

College of the City of New York

American Cotton Seed and Cottonseed Products

The cotton seed received at American mills during the nine-month period Aug. 1, 1919, to April 30, 1920, amounted to 3,963,472 tons, as compared with 4,218,135 tons in the corresponding period of 1919, according to a preliminary report of the Bureau of the Census. This does not include 23,725 tons and 40,438 tons on hand Aug. 1, nor 163,546 tons and 124,743 tons reshipped or destroyed for 1920 and 1919, respectively.

The amount of seed crushed during the nine-month period was 3,883,368 tons in 1920 and 4,084,719 tons in 1919. There was 103,829 tons on hand at the mills on April 30, 1920, as against 173,866 tons on April 30, 1919.

Imports of cottonseed products amounted to 18,285,430 tons during the nine months ended April 30, 1919. figures for the corresponding period of 1920 are not available.

Exports during this period totaled 125,826,786 lb. of oil, 210,641 tons of cake and meal, and 40,436 running bales of linters in 1920, against 129,847,205 lb. of oil, 119,054 tons of cake and meal, and 66,046 running bales of linters in 1919.

Electrochemical Notes From Scandinavia

New Soda Factory in Norway

Recently the Norwegian Hydro-Electric Saltpetre Co., which works the arc process at Notodden and Rjukan, has started a factory to make soda with which to combine the nitrous gases that pass over from the nitric acid absorption towers.

The plant has cost several million kroner and it starts with a production of 27 long tons per day. By it the company will be independent of outside sources of basic material and will be able to secure still further its position in the supply of pure sodium nitrate and sodium nitrite.

It is not generally known that for some years sodium nitrate has been made by the arc process in Norway and sold in England and elsewhere in competition with Chilean nitrate. The Norwegian product is readily absorbed by the market because of its exceptional purity.

Sodium Nitrite for Dye Industry

Sodium nitrite made by the electric arc process in Norway is again coming into the United States in quantity, a firm in New York City having contracted for at least 6,000 tons per annum for several years. The Norwegian Hydro-Electric Saltpetre Co. is easily able to control this trade because the sodium nitrite is of the nature of byproduct, inasmuch as it is made by the gases which are not absorbed to form nitric acid.

The Badische Anilin und Soda Fabrik established a factory at Christiansund about nine years ago for the special purpose of supplying its German dye-making plants with sodium nitrite.

The only factory making nitrites from arc in the United States is the Nitrogen Products Co. of Seattle; its output is in the form of sodium nitrite and most of it goes to dye works in Japan. Needless to say, the plant at Seattle is an arc plant.

Dr. Samuel Eyde

It will be of interest to engineers and electrochemists all over the world to learn that one of the new Ambassadors to Poland is the well-known Norwegian engineer, Dr. Samuel Eyde, whose persistence and large vision has done much to build up the great air nitrate plants at Notodden and Rjukan. Both Poland and Russia require immense quantities of nitrogenous fertilizers and it is not unlikely that this appointment may lead to very intimate trade relations with Norway, especially in these chemical products.

Carbide and Cyanamide Plants in Norway

A new cyanamide plant built in Norway during the war in which the Union Carbide Co. and McKlouman are interested has been closed down. It will probably not be restarted because the power—about 70,000 hp.—is being contracted out to various surrounding municipalities.

The position of carbide and cyanamide plants still running is chaotic and many are partly closed down so as to reduce their operating losses.

There seems to be no doubt that the synthetic methods of producing ammonia and the increasing production of byproduct ammonia will supplant the cyanamide method of making ammonia, a situation which would have occurred some time ago but for the war bringing about abnormal conditions, and preventing information coming from Germany as to the Haber process.

Swedish Cyanamide Co.

Recently there has been a considerable fall in market value of the shares of the Swedish Cyanamide Co. This is probably traceable to an invention of Dr. Cederberg of Stockholm University which has been purchased by the Norwegian Hydro-Electric Saltpeter Co. The invention has to do with the manufacture of ammonia and the Norwegian Hydro-Electric Saltpeter Co. is now working out the process in its experimental laboratories.

Before the war the Norwegian concern depended on England for ammonia with which to make ammonium nitrate and when the war made transport difficult it obtained ammonia from cyanamide made at Odda. It still uses some of this, but byproduct ammonia liquor is again going over from England in considerable quantity.

It is probable that the Norwegian company will some day make its own supply of ammonia.

Wages in Norway

In these days when so many people are wasting their time bewailing the tendency toward higher wages it will come as a surprise to find that some laborers in Norway are probably paid higher wages on the average than those in any other country in the world.

It is only comparatively a short time ago that boatloads of workers were leaving Norway to find homes and better paid occupations in the United States and Canada, and many cities have sprung up which are almost entirely populated by Scandinavian people.

The tendency now, however, is for Norwegians to remain in their own country because it is going ahead at such a very rapid rate and money has accumulated until now Norwegian financiers are prepared to back with ready cash practically any scheme that the electric engineers of that country place before them.

Use of Granulite in the British Glass Industry

The American Chamber of Commerce in London reports that an important discovery of granulite has been made, on the northern borders of Dartmoor, near Okehampton.

Granulite contains not only silica, but potash and soda—all of which are necessary in glass making—and gives the best results in the production of glassware of the highest quality. It is said that glass bottles and jars will be made cheaper here than anywhere in the world, as the cost of the material used on the spot will be only 15s. a ton, in comparison with the price of £2 a ton of the cheapest material ordinarily used. The material is reported as being specially suitable for the manufacture of cast and pressed glass articles and window glass. It is also of value in the manufacture of enameled metal ware and electrical insulators of various shapes. Even the waste heaps can be turned to account, for the black stone which was formerly considered suitable only for road material can now be used for making beer bottles (luckily, "Pussyfoot" has not yet been successful in England).

It is reported that English glass manufacturers will be in a position to compete on favorable terms in the neutral markets of the world.

Synopsis of Recent Chemical & Metallurgical Literature

Dehydrogenation of Primary and Secondary Alcohols by Catalytic Oxidation.—A general method of preparing aldehydes and ketones is given by CHARLES MOUREU and GEORGES MIGNONAC in *Comptes Rendus*, vol. 170, No. 5, pp. 258-261. During their work to transform secondary butyl alcohol into methylethylketone they have worked on the dehydrogenation by catalytic oxidation using first copper and then silver.

They have found that silver acts as an excellent catalyzer and that it can be used indefinitely, and they have generalized its use for the dehydrogenation of different alcohols. The catalyzer is prepared by precipitating the silver in a very finely divided state from the nitrate solution by formaldehyde on asbestos. The operation is as follows:

The catalyzer is placed in a tube and brought to a temperature of 230 to 300 deg. C. A thermocouple is introduced in the mass of the catalyzer to regulate the temperature within the required limits. In the mixture of air and alcohol vapors passing through the catalyzer the proportion of air is somewhat less than that theoretically required. Oxidation takes place immediately. The operation being exothermic, the temperature has to be controlled, because at higher temperatures the products formed are decomposed. To avoid this decomposition and to render the operation more regular they proceed by fractional oxidation with the use of two catalytic masses in series. A mixture of alcohol vapor and air in quantity notably inferior to the calculated quantity needed (40 to 50 per cent only) is passed over the first catalyzer mass; the products resulting are passed over the second catalyzer mass, where they meet the required supplement of air, and the final product is obtained. The operations are thus very regular, and the temperatures easily kept within the most efficient limits. In some cases there may be a series of more than two catalyzing masses.

They have treated nine alcohols and obtained the corresponding aldehydes and ketones with an efficiency of 60 to 96 per cent.

Treatment of Methyl Alcohol: Used two catalyzing masses, temperature maintained at 360-400 deg. C. Efficiency in formaldehyde 62 per cent. Carbon monoxide, hydrogen and carbon dioxide are present in the escaping gases.

Treatment of Ethyl Alcohol: Used two catalyzing masses, temperature maintained at 340-380 deg. C. Efficiency in acetaldehyde 89 per cent without any appreciable formation of acetic acid. In the escaping gases there are present 3 to 5 per cent carbon monoxide and 0.5 to 1 per cent carbon dioxide.

Treatment of Normal Butyl Alcohol: Used two catalyzing masses; temperature maintained at 330-350 deg. C. Efficiency in butanol 93 per cent.

Treatment of Amyl Alcohol: Used two catalyzing masses; temperature maintained at 330-350 deg. C. Efficiency in the corresponding aldehyde 94 per cent.

Treatment of Allyl Alcohol: Used one catalyzing mass, the quantity of air used being only two-thirds of that theoretically required. Efficiency in acrolein 70 to 75 per cent.

Treatment of Benzyl Alcohol: Used one catalyzing mass and a quantity of air less than that theoretically required so as to avoid an excessive increase in temperature of the catalyzer. When working at 300 deg. C. the proportion of the corresponding aldehyde obtained depends on the quantity of air used. During one passage about 40 per cent of the alcohol is transformed into aldehyde with an efficiency of 80 per cent of the transformed alcohol.

Treatment of Cinnamic Alcohol: Treated in the same manner as for benzyl alcohol. Efficiency in the corresponding aldehyde 60 to 70 per cent.

Treatment of Isopropyl Alcohol: Used one catalyzing mass. Efficiency in ketone 90 per cent.

Treatment of Secondary Butyl Alcohol: When using one catalyzing mass the efficiency in ketone is between 90 and 95 per cent. Better results are obtained by fractional catalyzing, when the operation is easier to handle, the production per given apparatus is increased and the efficiency is 2 to 3 per cent better. With a temperature of 350-400 deg. C. of the catalyzing masses, and with a quantity of air 10 per cent less than that theoretically required, the efficiency in ketone is 94 to 96 per cent; the escaping gases are composed of quite pure nitrogen containing only very small quantities of carbon monoxide and carbon dioxide.

Commercial Liquefaction of Gases.—At the April 16 meeting of the Syracuse Section of the American Chemical Society, CHARLES O. BROWN, of the Semet-Solvay Co., presented a paper on "Commercial Liquefaction of Gases." An abstract of this appeared in the April, 1920, issue of the *Syracuse Chemist*, which is the official bulletin of the Syracuse Section.

A short sketch was given of the historical development of the liquefaction of gases. The evolution of the research experiments into commercial apparatus was briefly described and the change from the early cycles used to those on which present theory is based was described in a general way.

In the production of nitrogen or oxygen, air is used as the source of these gases. After removing carbon dioxide by scrubbing, the air is compressed to 500 lb. per sq.in. by some systems, while others use only 350 lb. per sq.in.

Oil and caustic spray are removed from the compressed gas by mechanically baffling the gas after compression and cooling. The compressed gas is then liquefied and the liquid gas boiled, the vapor being separated by rectification in much the same way in which alcohol is produced. In some systems the rectifying column is under full pressure of the compressed gases, while in other systems it is under only a slight pressure, the gas having been expanded to produce the desired refrigeration. This expansion may be carried out by using a needle valve or by making the gas do work while expanding in some form of engine. This second cycle is more efficient for liquefaction than the first described. One system in use in this country uses both expansion accompanied by work for the larger proportion of gas and expansion without accomplishing work to a smaller extent. It was pointed out that by designing a suitable turbine the entire quantity of gas would be expanded in various stages of the turbine, accomplishing useful work and effecting a saving in costs as run at present.

Some costs were given for producing nitrogen, varying under different conditions between 8c. and 18c. per 1,000 cu.ft.

Monel as a Material for Internal Combustion Engine Valves.—To secure a valve material capable of giving satisfactory service under high temperature conditions has been one of the greatest problems in the development of the present-day aviation engine. In a recent paper presented to the English Institution of Automobile Engineers, the merits of different steels for this service are very fully discussed. There is, however, no mention of monel, a material which recent tests at the Bureau of Standards indicate to be deserving of serious consideration in this regard.

Exhaust valves of this material have given satisfactory performance in a 180-hp. Hispano-Suiza engine during 130 hours of running time, when tested by the Engine Section, Bureau of Standards. During the first 90 hours, the engine was devoted to tests made primarily for the study of lubricating oils and was operated for periods of about 6 hours each, during which time it was developing between 130 and 140 b.hp. at 1,800 r.p.m.

Examination of these valves at the end of 45 hours operation showed them to be badly pitted. They were ground just enough to reveal the condition of the valve seats, and these, too, were found badly pitted, although no considerable drop in power had been noted. During the next 45 hours, the horsepower was substantially the same as during the first 45, although a slight increase appeared during the first run following the replacement of the valves.

They were then subjected to 40 hours service under conditions far more severe than those encountered under normal conditions of operation. The engine was being used in a study of pre-ignition and for this purpose was operated at 1,800 r.p.m., full load, for periods of from 4 to 20 minutes. During the greater share of these runs pre-ignition was intentionally produced, resulting in extremely high engine temperatures. An evidence of these high temperatures was furnished in one instance by the fusing of the nichrome electrode of a specially prepared spark plug, the electrode's melting point being 1,500 deg. C. In spite of the severity of these tests, there was no evidence of power drop from leaky valves.

At the end of 130 hours of running time, valves and valve seats appeared to be no worse than at the end of the first 45 hours. The pitted appearance which seems to be a characteristic of this material has little effect on the gas tightness of the valve.

Analysis of Industrial Chlorbenzenes — Chlorbenzenes are of industrial importance not only in the manufacture of melinite, but also in the preparation of dyes. It is therefore necessary to have a practical method for their exact analysis. Raw chlorbenzene consists of a complex mixture in which predominate benzene, monochlorbenzene and paradichlorbenzene, whose boiling points are respectively 80, 130 and 172 deg. C. at normal pressure. F. BOURION has studied the problem of the analysis of the raw chlorbenzene and recommends the determination of its contents in benzene, monochlorbenzene and polychlorated benzenes (*Comptes Rendus*, April 19, 1920, pp. 933-935). He makes three fractional distillations.

The temperature limits for these three fractions are: the first between 80 and 130 deg. C., the second between 130 and 131.5 deg. C., and the third between 131.5 and 172 deg. C.

The residue of the distillation consists manifestly of polychlorated benzenes. The rectified second fraction is the pure chlorbenzene.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Recovery of Potassium Salts From Brines Containing Borax.—In recovering potassium from the types of brines found in Searles Lake or Owens Lake in California, the sodium borate in the solution has offered especial difficulties in the way of separation, owing to the fact that the relative solubilities of the two salts in hot and cold solutions is substantially the same. PARKER C. MCILHINEY of Great Neck, N. Y., effects a separation of potassium from associated salts by converting the chloride into the chlorate. This can be separated in a relatively pure state. In applying the process to water from Owens Lake it is best to remove the sulphate and carbonate of sodium and the major portion of sodium chloride. This is done by evaporation, with subsequent treatment with carbon dioxide, which converts the carbonate into the relatively insoluble bicarbonate, further evaporation causing a separation of practically all the sodium salts with the exception of a small amount of the chloride. The solution, containing potassium chloride and borax, is evaporated to a concentration at 90 to 100 deg. C., which corresponds to a saturated cold solution of potassium chloride. To the hot solution is added chlorate of sodium, calcium or magnesium in proper proportion, either in hot solution or solid form. Upon cooling the solution gradually, crystals of potassium chlorate will be deposited.

It is possible to produce a soluble chlorate within the solution by treating the solution, after removal of the sulphate of sodium, with chlorine. This reacts with the sodium carbonate forming sodium chlorate which in turn reacts to form potassium chlorate. (1,338,234; April 27, 1920.)

Purification of Zinc Solutions.—In order to obtain a successful deposition of zinc by electrolysis of a zinc sulphate solution impurities such as copper, cadmium, arsenic, antimony, iron, cobalt and nickel must be substantially eliminated. Satisfactory methods for the removal of all of the above-mentioned impurities have been developed with the exception of nickel and cobalt, the usual procedure being to agitate the solution with zinc dust at atmospheric temperature with air, or to treat in tube mills with zinc balls. This treatment does not remove nickel and cobalt completely.

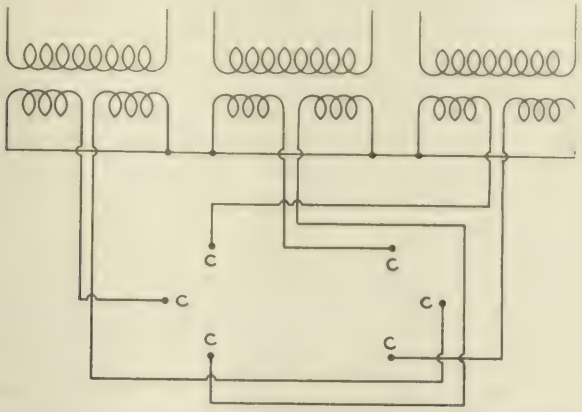
According to the present invention cobalt is removed by agitating the solution with lead peroxide or manganese dioxide. The cobalt is precipitated as the peroxide according to the equation:

$$2CoSO_4 + PbO_2 + H_2O = Co_2O_3 + H_2SO_4 + PbSO_4, \text{ or}$$

$$2CoSO_4 + MnO_2 + H_2O = Co_2O_3 + H_2SO_4 + MnSO_4$$

The solution is heated to between 80 and 100 deg. C., one part of reagent to 200 parts solution being used. Nickel can be removed by agitating with finely divided zinc at an elevated temperature. (1,336,386; H. LIVINGSTONE SULMAN and SAMUEL FIELD of London, England; assigned to Metals Extraction Corporation, Ltd.; April 6, 1920.)

Electric Blast Furnace.—In the operation of electric blast furnaces using three-phase current and producing heat by the ohmic resistance between electrodes entering the charge, one difficulty experienced in practice is that although the tension between any pair of diametrically opposite electrodes is constant, the tension between any other pair varies so that the current will also vary and cause corresponding variations in the heating zones of the furnace. This irregular heating produces deleterious effects on portions of the lining and roof. Also in case of accident



TRANSFORMERS AND CONNECTIONS FOR ELECTRIC BLAST FURNACE

to one electrode or its connections the particular phase between said electrode and the other electrode associated therewith will disappear.

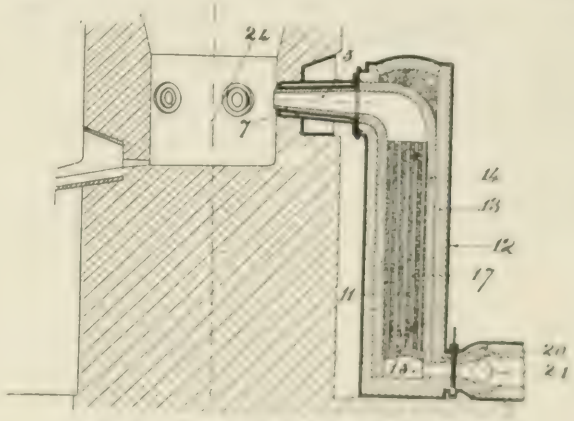
To overcome these disadvantages and also to produce uniform heating effect, JAMES BIBBY and JENS O. BOVING of London, England, utilize transformers and connections as shown in the accompanying sketch.

Three single-phase or a single three-phase transformer is employed and the neutral points of the three secondaries are connected together. Six electrodes *C* are employed, opposite pairs being connected to the same secondary winding. By connecting the windings in this way the several phases are anchored together, so that instead of three single independent phases there are virtually produced six phases of fixed and definite relationship. Consequently under normal conditions the heating is regular throughout the heating zones and the efficiency and life of the furnace are considerably enhanced. The disconnection of one electrode will not be as serious as when but three electrodes are employed. (1,336,017; assigned to Electro-Metals, Ltd.; April 6, 1920.)

Electric-Resistance Alloy.—The addition of approximately 10 per cent of titanium to an alloy consisting of 83 per cent nickel and 17 per cent chromium will produce an alloy having a specific resistance about fifty times that of copper. This alloy is durable and malleable and has a high melting point. Its specific resistance is higher than a nickel chromium alloy. (1,337,276; WILLIAM A. SCHENCH; assigned to Western Electric Co.; April 20, 1920.)

Electrically-Heated Melting Furnace.—Economy in metal and in furnace linings has resulted from the rotating of non-ferrous electric arc furnaces; the results obtained have become particularly apparent when melting brass or other alloys containing volatile constituents. A usual design of arc furnace is where the body of the furnace is in the form of a cylinder rotated in a horizontal axis by means of trunnions. L. C. HARVEY of Malden, England, has developed a furnace in the form of a flask rotated on an inclined axis. The removable electrode with the electrode holder is held stationary. Instead of using an electric arc the heat may be supplied by a heating element composed of resistance material. It is feasible to melt a metal having a high melting point by means of the arc and to continue the operation when alloying metals have been added by the resistance element, both types of electrodes being interchangeable. (1,337,839; April 20, 1920.)

Electric Resistance Furnace.—Cyclic utilization of gas, heated by means of an electric resistance furnace, to bring about endothermic reactions such as take place in blast furnaces or in furnaces for calcining carbonates is the subject of a patent issued to JULES SIMON and PAUL FRANCOIS SARRON of Lyons, France. The crucible, tuyeres and electric-resistance furnace are shown in the sketch. The tuyeres, 5, have a refractory lining, 7, of cast quartz or carborundum to withstand a temperature of 1,800 deg. C. This lining is inserted in a water-cooled jacket, 6. The furnace for heating the gas is formed of an outer metal shell, 12, a refractory lining, 13, and a refractory lining, 14, which is a poor conductor of electricity. Within this lining and resting on the arch, 15, is a resistance element, 11, formed from a highly refractory material and graphite and capable of being strongly heated by an electric current. In this resistance element are channels, 17, through which gas can be forced under pressure, thence through the tuyere into crucible 24 of the blast furnace. The working of the furnace is similar to that of an ordinary blast furnace, but the amount of carbon introduced with the charge is only that necessary to reduce oxides and a part of the carbonic acid, since the heat required is furnished by a cyclic gas, the latter coming from recuperators through conduit 21. On passing through the furnace charge the gas is diluted with the gaseous products



ELECTRIC RESISTANCE FURNACE

of the reactions and is passed through purifying apparatus, an amount of gas constituting the cyclic gas being sucked through heat regenerators and thence forced through the electric furnace.

The principal advantages obtained by this electric furnace are: Reduction of the amount of coke used, smaller consumption of electric energy, absence of nitrogen in cyclic gas, omission of electrodes, independence of the blast furnace proper from the electric furnace, making it possible to convert an ordinary blast furnace by the substitution of special tuyeres and the addition of the electric superheater. (1,334,809; March 23, 1920.)

in the Chemical and Metallurgical Industries

Dr. Frederick G. Cottrell Receives the Willard Gibbs Medal

The Chicago Section of the American Chemical Society held its annual banquet and presentation of the Willard Gibbs medal at the City Club, Friday evening, May 21. Dr. L. V. Redman, acting as chairman, in a short address introduced Dr. W. R. Whitney, who made the presentation.

Dr. Whitney did not attempt to recite the list of well-known achievements of Dr. Cottrell, nor call attention to his processes and products, but spoke rather of the high human quality of the recipient. He said that Dr. Cottrell was a pioneer who believed in opening unbeaten trails and keeping the coefficient of success to a high standard. The chemist can well appreciate the qualities of a man who believes in ideals. Dr. Cottrell has started many things which will well outgrow his own anticipation. His appointment as chief of the Bureau of Mines is gratifying to the men of the industry. In his new position we can forgive his mistakes if he keeps to his great ideals.

Dr. Cottrell Responds

"I have been deeply affected by Dr. Whitney's talk," replied Dr. Cottrell. "We have been colleagues many years. Knowing of no fresh piece of chemistry which I could bring as a message to this meeting, and being called upon somewhat hurriedly for a subject, I wired to Chairman Redman that I would speak on 'International Scientific Relations,' which would be broad enough to cover anything I might want to say. I want to express deep appreciation of the receipt of this beautiful medal, set in a wreath of cordial friendship and hearty welcomes as it is.

"The American chemist has a big field outside of his technical work. He is getting well into the activities of correlated subjects. The fact that he has scrambled over the border line and shown a human interest in parallel subjects is a good sign for his future.

"The experience of the war has served to illustrate the importance of the scientist in international affairs. The details of the Chemical Warfare Service are too well known to require mention here. War has furnished a great stimulus to the chemical industry, but this is only a prelude to the international character of the chemist's activities. The world has been awakened to a consciousness of the necessity for international contact. We have previously been isolated, but with 4,000,000 young men who have been thrown in contact with other peoples abroad at an impressionable age a world sense of international problems has been acquired which will form a deeper and more international life in the coming generation.

"The part the chemist plays in international relations is most important in both pure and applied chemistry. The work on international atomic weights is an illustration of the pure side and that of the International Congress of the applied side. The social side is further covered in personal courtesies like those between the New York Chemists' Club and the London and Paris Chemists' clubs. We will eventually have a chain of chemists' clubs in the international capitals of the world, which is a very inspiring thought.

"We must be sympathetic with the different views across the water, and when the American differs from them we must not arbitrarily try to reorganize European ideas. They are getting together in Europe to emulate our example of co-operation within the United States. The new industrial societies, as well as the academic chemists in Europe, are responding. There are many things to be overcome in France, such as the aloofness with which the older men view the younger in the industry.

"A central international patent office is being considered where patents after inspection may be filed in the various countries to operate under the laws of each. This will not interfere with primary patents in the country where they originated and will facilitate establishment abroad.

"The scientist can do much to help standardization throughout the world. There are many features affecting this. It is not so hard to adapt the metric system to the chemical and mining industries, where it is already used, but the civil and mechanical engineers are up against a different problem. These things should not be forced too much by legislation, but rather developed by education. Legislation should ever be confirmatory, as has been shown in the case of the last amendment to the Constitution.

"Another field for the chemist to consider is the question of raw materials. Petroleum is one of the well-known examples of this."

In conclusion Dr. Cottrell said: "Let the younger chemists have not only the technical problems to consider, but also that of public opinion, and the habit of such consideration should be acquired."

Industrial Research at Denver

The Denver Civic and Commercial Association has established an industrial research department in charge of Homer B. Vanderblue, former associate professor of transportation, school of commerce, Northwestern University, Chicago. The first activities of this research department will consist of a general survey of the situation with respect to surrounding territory, raw materials, transportation conditions and other industrial aspects. Investigations will also be undertaken along specific lines of industry, such as the manufacture of brass goods, metals and woolen goods.

Laboratory for Low Temperature Work Established

A cryogenic laboratory is to be established at once in Washington in connection with the helium work being done by the Bureau of Mines. The necessary funds for equipping the laboratory and conducting the work are being allotted to the Bureau of Mines from appropriations made to the Army and Navy Departments. The work in this new laboratory will be directed by R. B. Moore, the chief chemist of the Bureau of Mines.

The Federated American Engineering Societies

What appeared to be a most momentous gathering in engineering annals occurred in Washington June 3 and 4, at which time accredited representatives of nearly seventy national, local, state and regional engineering and allied technical organizations met to organize a permanent federation for welfare work by and for the engineer. It is impossible to recount at length the historical setting, and perhaps unnecessary. At least, it was noted editorially in CHEMICAL & METALLURGICAL ENGINEERING for May 26 that past events lent color to the belief that considerable opposition might be expected to the proposed plan to organize a federation of societies rather than an association of individuals.

Upon convening, however, it appeared essential to determine this debatable and fundamental question first of all. Consequently a very sharp debate occupied several hours' session over the following resolution:

> Resolved, That it is the sense of this conference that an organization be created to further the public welfare where technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions, and
>
> Resolved, That it is the sense of the conference that the proper organization should be an organization of societies and affiliations and not of individuals.

Naturally, the prime opposition came from the very able representatives of the American Association of Engineers, the foremost champion of the individualistic idea. As it appeared more and more certain, however, that the convention as a whole was determined to accept the resolution, on final roll call the A.A.E. representatives, leading alphabetically, voted aye. Of the fifty-seven societies represented in this session, five answered "present," and all the rest voted aye, 119 individual unanimous ballots being cast.

Then followed a continuous session of more than twelve hours, where the details of organization were worked out in committee on constitution and bylaws. This committee reported on the morning of the second day, and not until 3 o'clock in the afternoon was the constitution adopted, essentially as reported. Many divisions were taken, however, some determined by a narrow majority of two votes. On final roll call, of the sixty-seven societies represented, ten were absent, eight answered "present," and forty-nine voted to adopt, eighty-eight unanimous individual votes being cast. In answering "present," William J. H. Strong, of the American Association of Engineers, reviewed that body's criticisms of the constitution, but assured the meeting that whether their organization eventually joined the new federation or not they at all times stood ready to co-operate in all ways possible.

The constitution having thus been adopted, the bylaws were adopted as read, subject to editorial and legal revision of phraseology. Important sections of these documents follow:

CONSTITUTION

ART. I. NAME

The name of this organization shall be the Federated American Engineering Societies.

ART. II. OBJECT

The object of this organization is to further the interests of the public through the use of technical knowledge and engineering experience, and to consider and act upon matters common to the engineering and allied technical professions.

ART. III. MEMBERSHIP

Sec. 1. The membership shall consist of national, local, state and regional engineering and allied technical organizations and affiliations, classified as follows:

(1) National engineering and allied technical organizations.

(2) Local, state or regional engineering or allied technical organizations other than local associations, sections, branches or chapters of national organizations.

(3) Affiliations consisting of any one, or a combination of the following constituents.

(*a*) Local sections or associations of members of national organizations included under (1).

(*b*) Local engineering or allied technical societies or clubs, not of national scope.

(*c*) Local engineers and members of allied technical professions and their associates.

ART. IV. MANAGEMENT

American Engineering Council

Sec. 1. The management of this organization shall be vested in a body to be known as the "American Engineering Council," and its Executive Board.

Sec. 2. *Functions.* The American Engineering Council shall consist of representatives of member-societies selected as hereinafter provided. This Council shall co-ordinate the activities of state councils and of local affiliations whenever these activities are of national or general importance or may affect the general interests of engineers.

Sec. 3. *Representation.* Each national, local, state or regional organization or affiliation shall be entitled to one representative on the Council for a membership of 100 to 1,000 inclusive, and one additional representative for every additional 1,000 members or major fraction thereof; provided that in the determination of the representation of local, state or regional organizations or affiliations no count shall be taken of any organization which is represented individually or through another local, state or regional organization or affiliation; and provided further that no organization shall have more than twenty representatives on the Council.

Executive Board

Sec. 7. *Functions.* There shall be an Executive Board of thirty members of the Council charged with conducting the business of the organization under the direction of the Council.

Sec. 8. *Membership.* The Executive Board shall consist of thirty members, of whom six shall be the officers elected by the Council and twenty-four shall be selected, a part by the national societies, and the remainder by the local, state or regional organizations or affiliations according to districts, as provided in the bylaws; provided that the number of representatives of the national societies shall bear as near as may be the same ratio to the number of representatives of local, state or regional organizations or affiliations as the representation of the national societies bears to the representation of the local, state or regional organizations or affiliations.

ART. VI. FUNDS

Sec. 1. Funds for the use of the organization shall be contributed as follows:

(*a*) Each national society represented on the American Engineering Council shall contribute annually $1.50 per member.

(*b*) Each local, state or regional organization or affiliation represented on the Council shall contribute annually $1 per member.

No portion of such funds shall be applied to the use of local affiliations or state councils.

ART. VII. LOCAL AFFILIATIONS

Sec. 1. *Object.* The American Engineering Council shall encourage the formation of local affiliations to consider matters of local public welfare with which the engineering and allied technical professions are concerned, as well as other matters of common interest to these professions, in order that these may be united action and that suggestions and advice may be offered to the Council.

ART. VIII. STATE COUNCILS

Sec. 1. *Object.* State councils, consisting of representatives of local affiliations within the state or otherwise representative of the personnel of engineers and

members of allied technical professions in the state, if members of this organization, shall consider state matters of public welfare with which the engineering and allied technical professions are concerned, as well as other matters of common interest to these professions, in order that there may be united action in state affairs.

ART. IX. DELIMITATION OF AUTHORITY

Local affiliations, state councils and the American Engineering Council shall deal with local, state and national matters respectively, and they shall be autonomous with respect thereto.

ART. X. PUBLICITY

This organization shall stand for the principle of publicity and open meetings under such regulations as may be provided for in the bylaws.

BYLAWS

CHAP. I. MEMBERSHIP.

Sec. 1. *Qualifications.* Any society or organization of the engineering or allied technical professions is eligible for membership, the chief object of which is the advancement of the knowledge and practice of engineering or the application of allied sciences, and which is not organized for commercial purposes.

CHAP. II. MANAGEMENT

Sec. 1. *Terms of Representatives.* Representatives on the American Engineering Council shall serve for two years; provided that after the first election, where there is more than one representative from one organization, approximately half shall be elected each year.

Sec. 3. *Votes of Representatives.* Representatives on the Council and on the Executive Board shall each have one vote on these bodies.

Sec. 6. *Duties of Officers.* The Executive Officer shall be appointed and his compensation fixed annually by the Executive Board and shall hold office during its pleasure. He shall be the Secretary of the Council and of its Executive Board. He shall manage the business of the Council under the direction of the Executive Board, and perform such duties as may be assigned to him by the Council or the Executive Board. He shall be the custodian of the property of the Council. He shall collect all moneys due the Council and transfer them to the custody of the Treasurer. He shall scrutinize all expenditures and use his best endeavors to secure economy in the administration of the business of the Council. He shall certify to the accuracy of all bills or vouchers on which money is to be paid. He shall give a bond at the expense of the Council in amount and with surety satisfactory to the Board. He shall pay the current expenses of the office and for this purpose shall have at his disposal a suitable sum of money to be fixed by the Board, which amount shall be periodically replenished under the authority of the Finance Committee upon the representation of an amount of disbursements in the form required by it. He shall mail to the member-societies bills for their annual contributions thirty days prior to the beginning of the fiscal year. He shall perform such other duties as may from time to time be assigned to him by the Council or the Executive Board.

Sec. 8. *Duties of Executive Board.* It shall hold regular monthly meetings except during July and August.

The Executive Board, unless otherwise provided, shall appoint all special committees of the Council and of the Executive Board. The membership of such committees may be drawn from the membership of the Council or of the member-societies.

The Executive Board shall, whenever practicable, provide for the whole or a part of the expenses of representatives attending meetings of the Council and of the Executive Board.

Sec. 9. *Appointment of Committees.* Committees shall be appointed from the membership of the Board annually by the incoming president with the approval of the Executive Board, each member to serve one year, or until his successor is appointed.

Sec. 10. *Duties of Committees:*

The Committee on Publicity and Publication shall, when so requested, prepare all public statements and shall have the direction of publications of the Council.

The Committee on Membership and Representation shall report to the Executive Board on eligibility of each applicant for membership and the number of representatives to which it would be entitled. It shall review and report at least ninety days before each regular meeting of the Council the number of representatives to which each member-society is entitled. It shall review the existing electoral districts and report thereon to the Executive Board, at least once every two years. It shall report on all questions regarding registration and credentials of representatives on the Council.

The Finance Committee shall report an annual budget to the Executive Chairman and he or some other member of the committee shall countersign all checks for the payment of money.

The Committee on Public Affairs shall report to the Executive Board on all public affairs with which the engineer is concerned or which affect the relation of the engineer to the public.

CHAP. IV. PUBLICITY

Sec. 1. The privilege of attendance of all meetings of the American Engineering Council, of the Executive Board and committees, when not in executive session, shall be extended to any proper person, but this privilege does not extend the right to speak or vote. Any proper person shall have the right to inspect and make true copies of the records of all meetings of the Council, Executive Board and committees.

Fixed Nitrogen Corporation Bill Holds Position on Senate Calendar

In order that the bill creating the United States Fixed Nitrogen Corporation might enjoy the prestige of a position on the calendar it was reported favorably to the Senate just prior to adjournment. The original bill was changed in only one particular. Where it provided for the payment of the common stock subscription of $12,500,000 from the Treasury, the committee amended the bill as follows:

"In order to pay such subscription, as and when called, the Secretary of War is hereby authorized to sell so much as may be necessary of the supply of nitrate of soda owned by the United States and held as a reserve by the War Department, at such prices and under such regulations as may be prescribed by the Secretary of War. All sums realized from such sale are hereby appropriated to the use of the Secretary of War for the purchase of the preferred stock of the corporation."

Savannah Section of the A. C. S. Formed

By a waiver of jurisdiction from the Georgia Section of the American Chemical Society, as required by the action of the Council of the society on April 12 at St. Louis, Mo., a charter was granted on May 10 to a new section to be known as the Savannah Section and embracing the counties of Chatham, Effingham, Bryan, Liberty, Wayne, McIntosh, Glynn and Camden, Ga.

On May 27 the section was organized and the following officers were elected to serve for the balance of the year: President, J. J. McManus; vice-president, Maurice Siegel; secretary-treasurer, Herbert P. Strack; councillor, Dr. F. N. Smalley.

Prospects are promising for a live section.

German Dyes Imported

A shipment of German dyes consisting of 515 barrels and eight cases of assorted colors, consigned to the Textile Alliance, arrived recently on the steamer West Wauneke from Antwerp. These dyes had previously been allocated to various consumers and will not be put on the open market.

Nine barrels and forty-three cylinders of Swiss dyes consigned to four concerns arrived on the same ship.

Canadian Meeting Itinerary and Program of the American Institute of Chemical Engineers

Officially the Spring Meeting of the A. I. C. E. will open at 9 o'clock Monday morning, June 28, at the Hotel Windsor, Montreal, but a quorum of the navigators of the society will assemble beforehand on the S.S. Berkshire at Pier 32, North River, New York, sailing up the Hudson at 6 p.m. and arriving at Albany at 6 o'clock Sunday morning. The party will take the 7:20 D. & H. R.R. train to Lake George, where the S.S. Horicon will be boarded for Baldwin, which will give a delightful forenoon excursion. The S.S. Vermont will be taken at Montcalm Landing at 1:15 for Plattsburg, where the 7:15 train for Montreal will be met, giving the entire Sunday afternoon to the enjoyment of the rare beauty of the waters and shores of Lake Champlain.

Following is the program for the meeting:

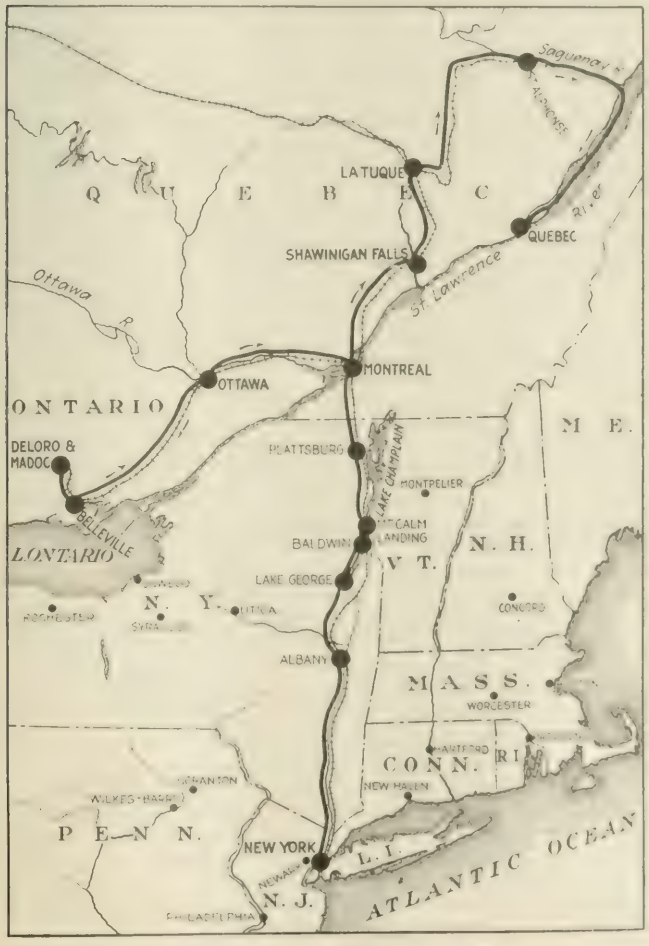
Monday, June 28

Meeting at Hotel Windsor, Montreal

9 A.M.—Business sessions, reports of Council, officers and committees.

10 A.M.—Reading of papers: address of welcome; "The Mann Report," A. W. Smith; "The Proposed National Department of Public Works," James R. Withrow; Symposium on Electrolytic Cells: "Early Commercial Electrolytic Cells," C. B. Barton; "The Fundamentals of Electrolytic Diaphragm Cells," H. K. Moore; "The Vertical Cylindrical Cell," L. D. Vorce; paper whose title has not yet been announced, A. H. Hooker.

2 P.M.—Reading of papers: "The Manufacture of Lime for Chemical and Metallurgical Purposes" (lantern slides), R. K. Meade; "The Evaporator Laboratory at the University of Michigan," W. L. Badger; "The Relation Between Temperature Drop and Heat Transmission in Vertical Tube Evaporators," W. L. Badger and P. W. Shepard; "The Relation Between the Boiling Point of Saturated Sodium Chloride Solution and Pressure," W. L. Badger and E. M. Baker; "The Relation Between Hydrostatic Head and Temperature Drop in Vertical Tube Evaporators," W. L. Badger and P. W. Shepard; "Experiments on the Corrosion of Iron and Steel," W. D. Richardson; "The Solution of Metals in Acids as Related to Corrosion," W. D. Richardson; "A Suggested Basis for an Index of Corrosion of Iron and Steel," W. D. Richardson.



ITINERARY OF THE A. I. C. E.

Tuesday, June 29

Meeting at Hotel Windsor

9 A.M.—Business sessions.

10 A.M.—Reading of papers: "Byproduct Coke Oven Industry," C. R. Bellamy; "American Progress in Dendro-Chemistry," H. O. Chute; "Industrial Application of Absorption" (illustrated by lantern slides), E. B. Müller; "The Sulphuric Acid Plant Fume Problem," J. R. Withrow and Frank C. Vilbrandt; "Chemistry of Rubber," Maximilian Toch.

2 P.M.—Visit to the glycerine refineries of Max & Rawolle, Ltd., by special street car.

8 P.M.—Meeting place to be announced. "Utilization of Peat," B. F. Haanel.

9 P.M.—Smoker at Windsor Hotel.

Wednesday, June 30

"Institute Special Train" will leave Ottawa for Belleville sufficiently early in the evening to pass through the scenic Rideau Lake District by daylight. Arrive at Belleville about 10:30 P.M. Train will be met on arrival by members of the Belleville Committee. Members who prefer to secure rooms at the Hotel Quinte should make reservations in advance to the Secretary, Dr. J. C. Olsen, or to Lucius E. Allen, Belleville, Ont.

Thursday, July 1

9:30 A.M.—Members will be taken for a motor drive about the city, visiting points of interest, and leave for Deloro, via Sterling and Marmora, viewing en route the Oak Hills and the Trent Valley.

11:30 A.M.—Arrive at Deloro. Inspection of the extensive works of the Deloro Smelting & Refining Co., Ltd., where the process of smelting and refining ores from the Cobalt region is carried out, producing cobalt, nickel and arsenic. Stellite metal is also produced by the electric furnace.

1 P.M.—A luncheon will be tendered all visiting members by the Deloro Smelting & Refining Co., Ltd., at its clubhouse.

2 P.M.—Leave for Belleville, via Madoc, at which point a short stop will be made at the plant of G. H. Gillespie & Co., miner and manufacturer of talc. There are also several fluorspar mines at Madoc.

4 P.M.—Inspection of the extensive plant of the Industrial Alcohol Co., Ltd., at Corbyville. This plant has been in operation since 1859 and in addition to manufacturing industrial alcohol, produces the famous "Corby Special Selected Rye Whiskey."

5.45 P.M.—Informal reception to members and their ladies at the Belleville Club. Light refreshments will be served.

7:30 P.M.—Complimentary dinner at the Hotel Quinte, tendered by the City of Belleville and the County of Hastings.

11:30 P.M.—Train for Shawinigan Falls.

Friday, July 2—At Shawinigan Falls

Visits to power house of the Shawinigan Water & Power Co.; plant of the Belgo Canadian Pulp & Paper Co., manufacturer of paper, ground wood, sulphite, etc.; plant of the Canada Carbide Co., manufacturing calcium carbide; plant of the Canadian Electro Products Co., manufacturer of acetaldehyde, paraldehyde and acetic acid. Entertainment for the ladies. Opportunity may be afforded for those who desire to stop at Grand Mere and visit the Laurentide Pulp & Paper Mill.

Saturday, July 3—At Latuque

Visit to sulphate pulp mill of the Brown Co. Fishing and boating at Wayagamac Club.

Sunday, July 4—At St. Alphonse

All-day steamer trip down the Saguenay River to Quebec. The Saguenay trip is one of the famous trips of the world and affords a view of the beautiful scenery on this river and also on the lower St. Lawrence.

Monday, July 5

Visiting the beautiful and historic City of Quebec.

Gas Men Convene to Consider Crisis of Their Industry

The emergency committee and members of the American Gas Association met Wednesday, May 26, in the Hotel Pennsylvania to consider ways and means to combat the shortage of basic raw material used in the manufacture of gas. With the great scarcity of coal, coke and gas oil the situation looks discouraging for the consumers as well as the manufacturers. Some of the plants have barely enough for present operations and all are wondering whether or not they will be able to operate during the coming winter.

Philip H. Gadsden, chairman of the emergency committee, said that the most important question was "how to keep the plants functioning to the consumer." With supplies of coal practically exhausted and supply of gas oil entirely inadequate for the purpose for which it is used, due largely to the increased demands for gasoline and kerosene, a most serious and critical situation confronts the gas manufacturers.

Résumé of Oil Situation

N. H. C. Smith, of the Bureau of Mines, gave a résumé of the oil situation in this country, and it certainly was not very encouraging. With the tremendous demand for gasoline by the automobile industry and the development of the Diesel type of oil engine, every possible means was being used to increase the supply. Higher fractions in the distillates for motor fuel robbed the gas oil, on the one hand, while the use of fuel oil for Diesel engines and oil-burning engines robbed it on the other, thereby increasing the cost and decreasing the supply of gas oil. It is estimated that Jan. 1, 1920, there were 7,500,000 automobiles and trucks in operation in the United States and that 1,500,000 would be added this year.

Oscar H. Fogg, secretary-manager of the association, said that although the growth of the various cities was increasing steadily, the limit of growth of gas companies has been hampered because the companies had no control over their income. Under regulated rates the average price of gas in 150 cities has advanced 15 per cent in the last five years, from $1.09 per 1,000 ft. in 1915 to $1.26 in 1919. During the same period all other commodities, necessities and luxuries have gone well above the 100 per cent mark.

After the addresses, the following resolutions were passed:

(1) To appoint a committee of seven to confer with representatives of the oil industry to obtain sufficient oil for the gas industry;

(2) To establish a differential in the selling price temporarily, to meet present emergency;

(3) To abolish the obsolete cp. standard.

Examination for Organic and Inorganic Chemist

The United States Civil Service Commission announces that an open competitive examination for organic and inorganic chemist, for men only, will be held July 6. Vacancies in the Philippine Service at $3,000 a year, and in positions requiring similar qualifications, at this or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer or promotion.

For further particulars apply to United States Civil Service Commission, Washington, D. C.

German Dye Companies Pay Big Dividends

The balance sheets of the large aniline dye companies of Germany show that in spite of the chaotic condition of business in general they at least are making money. The report of the Farbenfabriken vorm. Fr. Bayer & Co., Leverkusen, shows a net profit (at normal rate of exchange) of $5,725,000 as against $3,270,000 last year.

The Farbwerke vorm. Meister Lucius & Bruning, Höchst-am-Main, has a net profit of $6,050,000, as against $3,750,000 last year, and a dividend of 14 per cent, as against 12 per cent last year, is being paid.

It is said that the German coal-tar ring controls 40 per cent of the capital raised last December, which carries a double voting power in order to prevent the control passing into foreign hands. The Berlin Aniline Color Works is paying 18 per cent dividends, compared with 12 per cent paid last year.

Book Reviews

METALLOGRAPHY. PART I—PRINCIPLES. By *Samuel L. Hoyt.* New York: McGraw-Hill Book Co.; 251 pages; 1920. Price, $3.

This is Part I of the first edition of a treatise in three parts on Metallography; namely, Part I—Principles; Part II—The Metals and Common Alloys (in press); and Part III—Technical Practice (in preparation). It is the outgrowth, says the author, of a course of lectures delivered at the University of Minnesota, and judging by its scope and treatment may best be classed as an advanced textbook on the subject. In this first general part the usual topics are covered, including chapters on constitution diagrams, preparation of metallic alloys, metallic microscopy, microstructure of metals and alloys, pyrometry and thermal analysis, physical properties and mechanical properties. Although there is nothing essentially novel in the presentation and discussion of the subject matter, the author's conventional treatment of it is due primarily to the well-established nature of its facts and hypotheses which necessarily does not permit of radical departures in this direction. The whole subject has, however, been brought quite up to date in this Part I, and the student in the field will not fail to find in it the latest authoritative information on the topics covered; he will also find the discussion more thorough and detailed than in most other textbooks of this sort.

One or two features of the book warrant special mention. The rather difficult topic of constitution diagrams has been handled in a clear and yet sufficiently comprehensive manner which should be very satisfying to the student who is not at home in the subject and would otherwise be obliged to consult other more abstract and perhaps more systematic but certainly less vivid and less easily understood treatments. Much to be commended is the author's generous use of footnote references to the best original literature; the reader will not likely get the erroneous impression that this small volume represents the confines of our knowledge on the subject, but will be stimulated to further reading and search. The illustrations are uniformly excellent and this is particularly true of the photomicrographs, which are unusually fine.

The impression is obtained that the author in the paragraphs dealing with metallographic apparatus has not always given apparatus of American manufacture the prominence which in view of its recent development it really deserves. This naturally detracts somewhat from the practical usefulness of these paragraphs.

Part I of this text certainly justifies us in awaiting the publication of the complete work with much interest and anticipation. Paul D. Merica

Personal

H. W. DAHLBERG, of the Great Western Sugar Co., Denver, Col., is now manager of the research department, which has been combined with the statistical department.

W. C. GRAHAM, formerly manager of the research department of the Great Western Sugar Co., Denver, Col., has resigned to take entire charge of the various plants of the American Potash Co. at Antioch, Neb.

ELLWOOD HENDRICK, consulting editor of CHEMICAL & METALLURGICAL ENGINEERING, delivered an address before the Delaware Section of the American Chemical Society, Delaware State College, Newark, Del., on "Chemistry and Civilization," on May 29. On June 12 he will deliver the address to graduates of the Rose Polytechnic Institute, Terre Haute, Ind., at the commencement exercises.

Dr. ARTHUR LACHMAN, of San Francisco, whose mysterious disappearance last December was the cause of grave concern on the part of his friends, was found May 19 on a train en route to San Francisco and is now at his home.

W. LEE LEWIS, professor of chemistry, Northwestern University, will succeed Dr. Willard as chairman of the Chicago Section of the American Chemical Society.

Dr. GEORGE A. PERLEY, of New Hampshire College, has been at Copper Hill, Tenn.

M. J. PROFFITT, formerly of the Great Western Sugar Co., Denver, Col., is now in charge of the sugar technology division at the Bureau of Standards, Washington, D. C.

Dr. F. H. RHODES has resigned the position of director of research for the chemical department of The Barrett Co., at Frankford, Pa., in order to accept the appointment as professor of industrial chemistry in Cornell University.

Provost EDGAR SMITH of the University of Pennsylvania tendered his resignation to the board of trustees, which has been accepted. Dr. Smith presented his resignation last February. In accepting it now the board makes him emeritus professor of chemistry and places at his disposal the Harrison laboratory, where Dr. Smith expects to devote the greater part of his time to research work.

L. I. SHAW, assistant chief chemist for the U. S. Bureau of Mines, Washington, D. C., and R. T. Stull, chief ceramist for the Bureau and in charge of the station at Columbus, Ohio, have been visiting Western stations at Golden, Col., Salt Lake City, San Francisco and Seattle.

E. T. STANNARD, vice-president of the Alaska Steamship Co., has been elected a vice-president of the Kennecott Copper Corp. Mr. Stannard will move his headquarters from the mines at Kennecott to Seattle, Wash.

F. W. WILLARD, of the Western Electric Co., has transferred his activities to the planning of a new transoceanic cable plant for his company at Norfolk, Va.

C. E. WILLIAMS, who was recently assigned to electrometallurgical work at the Seattle Station of the Bureau of Mines, has reached Seattle after making a tour of the electrometallurgical centers of the East.

Obituary

GEORGE GILBERT POND, dean of the School of Natural Science of Pennsylvania State College, died at Hartford. He was born in Holliston, in March, 1861. For five years he was instructor in chemistry at Amherst and then became a professor in the same department. He left Amherst to accept the appointment with the Pennsylvania State College.

EDMUND GYBBON SPILSBURY, mining and metallurgical engineer of note, president of the E. G. Spilsbury Engineering Co. and former president of the Engineers' Club of New York and of the American Institute of Mining and Metallurgical Engineers, died suddenly May 28 of heart failure in the New York Eye and Ear Infirmary following an operation for cataract a few days previously.

Current Market Reports

The Non-Ferrous Metal Market

New York, June 7, 1920.—There have been few important changes in the non-ferrous metal market. Copper declined ½c., while tin strengthened slightly. Lead, also, is firmer.

	Cents per Lb.
Copper, electrolytic	15 50
Aluminum, 98 to 99 per cent	12 [illegible]
Antimony, wholesale lots	[illegible]
Nickel, ordinary	4 [illegible]
Nickel, electrolytic	4 [illegible]
Tin, Straits, spot	[illegible]
Lead, New York, spot	[illegible] 7 25
Lead, E. St. Louis, spot	[illegible] 50
Zinc, spot, New York	7 85
Zinc, spot, E. St. Louis	7 50

OTHER METALS		
Silver	oz.	$0.9925

Zinc, scrap	5 00@5 25

The Iron and Steel Market

Pittsburgh, Pa., June 3, 1920.

The improvement in rail traffic conditions that began two or three weeks ago is now proceeding at a more rapid pace. It is not a case of strikers returning to work, as the strike itself was practically ended some time ago, but rather of new men becoming more accustomed to their work, of team work by the railroads, under the direction of the Interstate Commerce Commission, having an effect, and of the natural tendency of a rail congestion to diminish more and more rapidly. In previous cases of traffic congestion the railroads would labor for a long time without apparent results, but when improvement once began it would proceed more and more rapidly.

There are few points now that cannot be reached by rail shipments, if the shipment can once be started. With many steel consumers the point is not to receive fresh shipments from mills, but rather to get shipments that were put on the rails long ago and stalled somewhere en route. As to car supplies, they are still meager, but practically all plants report more or less improvement in placements. Of notable assistance in improving the position of the iron and steel industry has been the partial resumption of the Pittsburgh & Lake Erie, so important to the Youngstown district. The road is still not doing a great deal in handling carload freight, but solid through freight train movement is fairly heavy. As a result largely of improvement on the Pittsburgh & Lake Erie, operations in the Youngstown district at blast furnaces at steel mills, though hardly at finishing mills, are now at about 70 per cent.

The steel industry has hardly attained the point yet of making shipments equal to its current production, but such a point does not seem to be far distant now, and when that is attained the mills must address themselves to the movement of the large amount of steel that has accumulated. Except for a moderate tonnage of ingots and billets, all the steel accumulated has been on order. What effect upon the attitude of consumers the movement of so much steel will have remains to be seen. Ever since the beginning of the rail strike it has been notable that while consumers of steel in general were incommoded, they did not seem to be incommoded as much as one would expect from the great reduction in steel receipts.

Market Prospects

The pig iron, unfinished steel and finished steel markets are all very dull, the condition having become more pronounced week by week. The attitudes of buyers and sellers are just what they usually are in such a combination of circumstances. Buyers, having been very nervous earlier in the year for fear they would not secure all the steel they expected to need and having bid up prices with all the mills that were desirous of obtaining as high prices as possible, are now nervous in the other direction, and will buy nothing but what they are absolutely certain they will need. A few are even thinking about reselling stocks and material due them, in expectation that they may be able to replace the material later on, though they cannot now, at lower prices.

Producers Indisposed to Reduce Prices

As usual, the producers are indisposed to reduce prices merely because their sales are lighter than formerly. As long as the steel producer has unfilled tonnage on books he is disposed to stand firm, for to cut prices to effect forward sales starts a disturbance in the market and by the time the delivery period arrives the buyer may have still better offers. Roughly speaking, the steel mills are sold ahead in inverse ratio to the prices they have been charging, the Steel Corporation farthest ahead, say seven or eight months as an average for all products, the large independents for from two to five months, and the small independents for shorter periods. Thus it is the highest priced mill that first has occasion to make its prices more attractive, but the price cut is the highest price, and the prices asked for farther forward deliveries are not necessarily affected. Black sheets for prompt shipment, for illustration, brought as high as 10c. toward the close of February and about 9c. a month ago, while now they can be had for about 7.50c. Independents that are sold up for from two to three months ahead, however, have only been quoting between 5c. and 6c. and their position is not necessarily disturbed, while the Steel Corporation, with its Industrial Board price of 4.35c., is not concerned whatever in the matter.

Pig Iron

The market in pig iron continues to be confined to small lots for early or spot shipment, and thus the test of values for far forward deliveries, such as are ordinarily contracted for in a strong market, is entirely lacking. Prompt bessemer recently brought $43, valley, in small lots, as against $42.50 formerly quoted, making "the market," such as there is, quotable at $43, valley. Foundry continues quotable at $45, valley. Basic, which seemed to be established at $43.50, is reported to have sold at $43 in one or two instances. The furnaces are well sold up for a few months, on the basis of customers taking full deliveries according to contract.

Semi-Finished Steel

Billets are in no request and prices are simply nominal as last done in actual transactions, $60 to $65 for standard billets and $70 for small billets. Sheet bars are in light demand, makers quoting $70 to $75 on bessemer and $75 to $80 on open-hearth. There is a fair demand for slabs, with offerings light, except of blooming-mill slabs. Rods are in moderate demand, at $70 to $75, but not as active as two or three weeks ago.

Ferro-Alloys

The pressure for prompt ferromanganese has subsided and the market is not strong at the previous quotation of $250, delivered. Contract alloy remains at $200, delivered. Spiegeleisen is quiet at $72.50@$75, furnace, for prompt or forward. Electrolytic ferrosilicon is inactive, prices being largely nominal at about $78@$80 for 50 per cent and $150@$155 for 75 per cent, delivered. Bessemer ferrosilicon remains at $62.50 for 10 per cent, $65.80 for 11 per cent and $69.10 for 12 per cent, f.o.b. furnaces at New Straitsville and Jackson, Ohio.

The Chemical and Allied Industrial Markets

New York, June 4, 1920.

There has been very little activity in the chemical market during the period, with whatever buying that has been done confined to small orders. The general impression seems to be that the transportation situation is easier and points to recovery soon, although producers are still having difficulty in obtaining raw materials for the manufacturing of the finished product. The firmness noted throughout the *acid* list for some time back is well sustained, while *muriatic,* 20 deg., which is very scarce, has been sold as high as $3.50@$4.50 per cwt. during the week. There has been no actual change in *acetic,* 99½ per cent glacial, but the average price is now nearer $17 than it has been for the past few weeks. *Caustic potash* is on the decline and sales have been heard of around 27c. per lb., but business on this item has been very small and producers are gradually recovering from the recent difficulties with labor and transportation. *Soda ash* remains in the same nominal position, with very little material being offered on the spot market at prices ranging between $3.50 and $4 per cwt. There are some resale American goods being offered by Japan at figures below the present market. These offerings are for contracts at $3@$3.50 per cwt., but buyers are not disposed to take chances on future delivery. *Caustic soda* is in practically the same position, $6.25@$6.50 per cwt. being the prevailing nominal quotations, with offerings coming in from Japan at figures slightly under this price.

Coal-Tar Products

Although there have been some few declines during the period, the long expected break has not yet arrived. In general former quotations hold, with very little material changing hands, and that in a small way. Japan at present is a factor in this market and is offering material at prices below those quoted here, but consumers seem to be sitting tight watching for the long-promised upheaval in the domestic market. *Dimethylaniline* is now back on the market after a considerable absence and offerings range between $1.25 and $1.50 per lb., against a range of $1.50 to $1.60 of the previous week. *Aniline oil* dropped to a new level and is now to be had at 42@48c. per lb., compared with 45@50c., the recently prevailing figure.

Naval Stores

This market continues dull, with very small offerings being made in the *rosins.* Former prices still hold nominally, as shipping conditions from Savannah are still retarding the arrival of material in this port. *Turpentine* is now in fairly good supply and further arrivals are expected shortly. The current price in the New York market is around $1.95 per gal., which, compared with the top figure of $2.35 of last week's report, represents a considerable drop in this item.

Crude Rubber

The unsettled conditions of the money market, combined with a holding back on the part of the large rubber consumers, have brought about the listless condition of this market. *Rubber* has been on a steady decline for some time past and the absence of the usual fluctuating prices, added to the fact that present spot quotations are below future offerings, emphasizes the absolute lack of activity in the trade.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	$0 65 – $0 75	
Acetone	lb.	$0 15 – $0 20	21 – 22

Barium dioxide (peroxide)	lb.	.21 – .23	24 – .25
Barium nitrate	lb.	.09½ – 11	.11 – 12
Barium sulphate (precip.) (blanc fixe)	lb.	.04½ – .05	.05½ – .06
Bleaching powder (see calcium hypochlorite)		– –	
Blue vitriol (see copper sulphate)		– –	
Borax (see sodium borate)		– –	
Brimstone (see sulphur, roll)		– –	
Bromine	lb.	.70 – .90	1.00 – 1 05
Calcium acetate	cwt.	3.50 – 3.55	
Calcium carbide	lb.	04½ – 04½	04½ – 05½
Calcium chloride, fused, lump	ton	23.00 – 25.00	30 00 – 40 00
Calcium chloride, granulated	lb.	01½ – 01¾	02 – 02¼
Calcium hypochlorite (bleaching powder)	cwt.	4.00 – 4.25	4 50 – 5 50
Calcium peroxide	lb.	– –	1 50 – 1 70
Calcium phosphate, monobasic	lb.	– –	75 – 80
Calcium sulphate, pure	lb.	– –	25 – 30
Carbon bisulphide	lb.	.08 – .09	10 – 11
Carbon tetrachloride, drums	lb.	.11 – .11½	12 – 15½
Carbonyl chloride (phosgene)	lb.	– –	80 – 1 05
Caustic potash (see potassium hydroxide)		– –	
Caustic soda (see sodium hydroxide)		– –	
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.09 – .09½	.10 – 10½
Chloroform	lb.	.30 – .35	.36 – .38
Cobalt oxide	lb.	– –	2.00 – 2.05
Copperas (see iron sulphate)		– –	
Copper carbonate, green precipitate	lb.	.27 – .28	.29 – .31
Copper cyanide	lb.	– –	.65 – .70
Copper sulphate, crystals	lb.	.08 – .09	.09 – .09½
Cream of tartar (see potassium bitartrate)		– –	
Epsom salt (see magnesium sulphate)		– –	
Ethyl Acetate Com. 85%	gal.	1.35 –	1 40 –
Ethyl Acetate pure (acetate ether 98° to 100°)		– –	1 75
Formaldehyde, 40 per cent (nominal)	lb.	.36 – 40	57 – .65
Fusel oil, ref.	gal.	– –	5.25 – 6 00
Fusel oil, crude (nominal)	gal.	– –	
Glauber's salt (see sodium sulphate)		– –	
Glycerine	lb.		26½ – 28½
Iodine, resublimed	lb.	4 30 – 4 35	4.40 – 4 45
Iron oxide, red	lb.	– –	.03 – .20
Iron sulphate (copperas)	cwt.	1 50 – 1 75	1.80 – 2 00
Lead acetate, normal	lb.	– –	13½ – 15½
Lead arsenate (paste)	lb.	11 – 12	.13 – 17
Lead nitrate, crystals	lb.	– –	.90 – 1.00
Litharge	lb.	.14 – .15	15½ – .16
Lithium carbonate	lb.	– –	1.50 –
Magnesium carbonate, technical	lb.	.12 – .14	.15 – 16
Magnesium sulphate, U. S. P.	100 lb.	3.00 – 3.55	4.00 – 4.50
Magnesium sulphate, commercial	100 lb.	– –	3.25 – 3.60
Nickel salt, double	lb.	– –	.14 – .16
Nickel salt, single	lb.	– –	.16 – .18
Phosgene (see carbonyl chloride)		– –	
Phosphorus, red	lb.	.50 – .55	.60 – 65
Phosphorus, yellow	lb.	– –	.35 – .37
Potassium bichromate	lb.	.35 – .37	45 – .46
Potassium bitartrate (cream of Tartar)	lb.	.52 – .56	.57 – .58
Potassium bromide, granular	lb.	.80 – .85	.90 – 95
Potassium carbonate, U. S. P.	lb.	– –	.85 – .88
Potassium carbonate, crude	lb.	.21 – 28	.26 – .28

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities

		Carlots	Less Carlots
Alpha naphthol, crude	lb.		$1 25
Alpha naphthol, refined	lb.		1.45
Alpha naphthylamine	lb.	65 –	70
Aniline oil, drums extra	lb.	15 –	20
Aniline salts	lb.	42 –	50
Anthracene, 80% in drums (100 lb.)	lb.	80 –	1 00
Benzaldehyde (free)	lb.	2 00 –	2 10
Benzidine, base	lb.	1 35 –	1 40
Benzidine, sulphate	lb.	1 20 –	1 25
Benzoate of soda, U. S. P.	lb.	95 –	1 10
Benzoate of soda, U. S. P.	lb.	85 –	1 00
Benzol, pure, water-white, in drums (100 lb.)	gal.	27 –	30
Benzol, 90%, in drums (100 lb.)	gal.	25 –	31
Benzyl chloride, 95-97%, refined	lb.	35 –	40
Benzyl chlorides, tech.	lb.	25 –	35
Beta naphthol benzoate (nominal)	lb.	90 –	95
Beta naphthol, sublimed (nominal)	lb.	80 –	85
Beta naphthol, tech (nominal)	lb.	67 –	85
Beta naphthylamine, sublimed	lb.	2 35 –	2 40
Cresol, U. S. P., in drums (100 lb.)	lb.	18 –	40
Cresol, ortho, in drums (100 lb.)	lb.	25 –	35
Cresylic acid, 97-99%, straw color, in drums	gal.	1 10 –	1 20
Cresylic acid, 95-97%, dark, in drums	gal.	1 00 –	1 05
Cresylic acid, 50%, first quality, drums	gal.	65 –	75
Dichlorbenzol	lb.	08 –	10
Diethylaniline	lb.	–	1 80
Dimethylaniline	lb.	1 25 –	1 30
Dinitrobenzol	lb.	20 –	27
Dinitrochlorbenzol	lb.	10 –	15
Dinitronaphthaline	lb.	40 –	55
Dinitrophenol	lb.	90 –	95
Dinitrotoluol	lb.	40 –	45
Diphenylamine (nominal)	lb.	45 –	46
Dyphenylene oxide (nominal)	lb.	–	85
Hexalin (concrete)	lb.	2 25 –	2 30
Metadinitrobenzene	lb.	1 15 –	1 20
Monochlorbenzol	lb.	–	15
Monomethylaniline	lb.	1 –	1 85
Naphthalene, crude	lb.	–	05
Naphthalene, flakes (250 lb.)	lb.	05½ –	12
Naphthalene, salts	lb.	15 –	18
Naphthionate of soda, crude	lb.	75 –	80
Nitrobenzol	lb.	14 –	16
Nitronaphthaline	lb.	40 –	50
Nitrotoluol	lb.	30 –	35
Orthodichlorbenzol	lb.	8 –	4 00
Orthodinitrobenzol	lb.	–	1 25
Orthonitrophenol	lb.	–	2 50
Orthonitrotoluol	lb.	15 –	45
Orthotoluidine	lb.	55 –	65
Paradichlorbenzol, block	lb.	15 –	18
Paranitraniline, 100%	lb.	1 60 –	1 70
Paranitrophenol, 100%	lb.	1 –	1 10
Paranitrotoluol	lb.	08 –	12
Paraphenylenediamine	lb.	1 65 –	1 75
Paratoluidine	lb.	1 10 –	1 20
Paratoluolsulphonamide	lb.	1 60 –	3 00
Pentachlorphenol	lb.	1 00 –	1 10
Phthalic anhydride	lb.	70 –	75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	17 –	20
Pyridin	gal.	3 00 –	3 50
Resorcin, crude	lb.	4 15 –	4 30
Resorcin, pure	lb.	5 75 –	6 25

Salicylic acid, tech., in bbls. (110 lb.)	lb.	$0.50 —	$0.52
Salicylic acid, U. S. P.	lb.	.50 —	.60
Salol	lb.	.90 —	1.00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 —	.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.28 —	.32
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.36 —	$0.39
Beeswax, refined, light	lb.	.39 —	.40
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	1.00 —	1.05
Carnauba, No. 2, regular (nominal)	lb.	.85 —	.88
Carnauba, No. 3, North Country (nominal)	lb.	.44 —	.45
Japan	lb.	.21 —	.22
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09½ —	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11½ —	.12
Paraffine waxes, refined, 128-130 m.p.	lb.	.13 —	.14
Paraffine waxes, refined, 133-135 m.p.	lb.	.15½ —	.16½
Paraffine waxes, refined, 135-137 m.p.	lb.	.17½ —	.18½
Stearic acid, single pressed	lb.	.25 —	.26
Stearic acid, double pressed	lb.	.26 —	.27
Stearic acid, triple pressed	lb.	.28 —	.29

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.75
Pine oil, pure, dest. dist.	gal.	1.60
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$19.00 —	$20.30
Rosin E-I	280 lb.	20.30 —	20.50
Rosin K-N	280 lb.	20.50 —	22.00
Rosin W. G.-W. W.	280 lb.	22.50 —	23.00
Wood rosin, bbl.	280 lb.	17.80 —	18.50
Spirits of turpentine	gal.	1.90 —	1.95
Wood turpentine, steam dist.	gal.	..... —	.....
Wood turpentine, dest. dist.	gal.	1.90 —	2.00
Pine tar pitch, bbl.	200 lb.	..... —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	15.00
Retort tar, bbl.	500 lb.	15.00 —	15.50
Rosin oil, first run	gal.	.87 —	.89
Rosin oil, second run	gal.	.89 —	.92
Rosin oil, third run	gal.	1.04 —	1.05
Rosin oil, fourth run	gal.	1.12 —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.40
70-72 deg., steel bbls. (85 lb.)	gal.	.38
68-70 deg., steel bbls. (85 lb.)	gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.29

Crude Rubber

Para—Upriver fine	lb.	$0.37½ —	$0.38
Upriver coarse	lb.	.28¾ —	.29½
Upriver caucho ball	lb.	.30 —	.30½
Plantation—First latex crepe	lb.	.38 —	.39
Ribbed smoked sheets	lb.	.38¾ —	.39
Brown crepe, thin, clean	lb.	.37 —	.38
Amber crepe No. 1	lb.	..... —	.40

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.18½ —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.22
China wood oil, in bbls.	lb.	.22½ —	.23½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.17½ —	.18½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.18½ —	.19½
Corn oil, crude, in bbls.	lb.	.17½ —	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.15½ —	.16
Cottonseed oil, summer yellow	lb.	.19 —	.19½
Coteonseed oil, winter yellow	lb.	.21 —	.22
Linseed oil, raw, car lots (domestic)	gal.	1.65 —	.....
Linseed oil, raw, tank cars (domestic)	gal.	1.60 —	.....
Linseed oil, boiled, car lots (domestic)	gal.	1.67 —	.....
Olive oil, commercial	gal.	3.10 —	3.25
Palm, Lagos	lb.	.12½ —	.13½
Palm, bright red	lb.	.13 —	.13½
Palm, Niger	lb.	.11 —	.12
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.16½ —	.17½
Peanut oil, refined, in bbls.	lb.	.22 —	.24
Rapeseed oil, refined in bbls.	gal.	1.70 —	1.72
Rapeseed oil, blown, in bbls.	gal.	1.80 —	1.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.17 —	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.13 —	.13½

FISH

Winter pressed Menhaden	gal.	$1.17 —	$1.18
Yellow bleached Menhaden	gal.	1.20 —	1.22
White bleached Menhaden	gal.	1.23 —	1.24
Blown Menhaden	gal.	1.30 —	1.32

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	$20.00 —	$22.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	16.00 —	18.00
Barytes, crude, 88%@94% ba., Kings Creek	net ton	8.00 —	10.00
Blanc fixe, dry	lb.	.05½ —	.06
Blanc fixe, pulp	ton	60.00 —	80.00
Casein	lb.	.15 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	.05 —	.06
Chalk, English, dense	lb.	.04½ —	.05
China clay (Kaolin) crude, f.o.b. Pkin, Va.	net ton	8.00 —	12.00
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
Feldspar (nominal) f.o.b. N. Y. State	ton	13.50 —	18.00
Feldspar, crude, f.o.b. Maryland and North Carolina, points	net ton	7.50 —	8.00
Feldspar, ground, f.o.b. Baltimore	net ton	18.00 —	25.00
Fire clay, f.o.b. Baltimore	net ton	5.00 —	7.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Graphite (dust polish grade 30%) Ashland, Ala.	lb.	..... —	0.01
Graphite (dust facing grade 50%) Ashland, Ala.	lb.	..... —	0.01½
Graphite, crucible, 85% carbon Ashland, Ala.	lb.	..... —	.07
Graphite, crucible, 90% carbon Ashland, Ala.	lb.	..... —	.08½
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	.....
Quartz (acid tower) fist to head, f.o.b. Baltimore	net ton	..... —	10.00
Quartz (acid tower) 1½@2 in., f.o.b. Baltimore	net ton	..... —	14.00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton	..... —	17.00
Shellac, orange, fine	nominal lb.	1.50 —	.....
Shellac, orange, superfine	lb.	1.60 —	1.65
Shellac, A. C. garnet	lb.	1.30 —	1.35
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	20.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. Works:

Chrome brick	net ton	$75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	85-90 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.22
Ferro-manganese, 70-80% Mn.	gross ton	200.00 —	250.00
Spiegeleisen, 16-20% Mn.	gross ton	73.00 —	75.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.25 —	2.75
Ferro-silicon, 50%	gross ton	80.00 —	90.00
Ferro-silicon, 75%	gross ton	150.00 —	200.00
Ferro-silicon, 10-15%	gross ton	60.00 —	65.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90 —	1.10
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50 —	7.75

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3 f.o.b. Atlantic Seaboard	unit	$0.70 —	$0.85
Coke, foundry, f.o.b. ovens	net ton	15.50 —	16.50
Coke, furnace, f.o.b. ovens	net ton	14.50 —	15.50
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	24.00
Fluor spar, gravel, f.o.b. mines	net ton	25.00 —	30.00
*Fluor spar, acid grade, lump, f.o.b. Tonuco, Mex.	net ton	30.00 —	45.00
*Fluor spar, acid grade, ground, f.o.b. Tonuco	net ton	55.00 —	65.00
Manganese ore, 45% Mn and over	unit	.80 —	.95
Manganese ore, chemical (MnO_2)	gross ton	80.00 —	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00 —	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50 —	7.50
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	12.00 —	14.00
Vanadium Ore	lb.	1.00 —	3.00
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.01½ —	.02
Rutile, 95% TiO_2	lb.	.15 —	.25
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

*Nominal

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in	100 lb.	$2.45@ $4.00
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45@ 4.00
Tees, 3-in. and larger	100 lb.	2.45@ 4.00
Plates	100 lb.	2.65@ 4.00
Rivets, structural, ¾-in. and larger	100 lb.	4.50
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.60
Sheets, No. 28 black	100 lb.	4.35@ 6.50
Sheets, No. 10 blue annealed	100 lb.	3.55@ 6.00
Sheets, No. 28 galvanized	100 lb.	5.70@ 8.50

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

PHOENIX—V. A. Thompson, city mgr., will receive bids until June 16 for the installation of a complete infiltration intake system.

California

BISHOP—The Bishop Union High School Dist. received bids for the construction of a 2-story high school from R. W. Moller, Call-Post Bldg., San Francisco, $150,846; Young & Nunamaker, Bishop, $151,800. Laboratory equipment will be installed in same.

BURBANK—The Burbank Development Co., 206 West San Fernando St., is having plans prepared for the construction of 2 soap factory buildings on Verdugo Ave. Soap-making machinery will be installed in same. Estimated cost, $200,000.

LONG BEACH—The city received bids for the construction of a sewage pumping plant with pumps, motors, flush tanks, etc., from John Cummings, 1200 Washington Bldg., Los Angeles, $44,650; John Radick, $46,999; Peter Tomick, $57,900. A. DeRuiz, engr.

LOS ANGELES—The Miller Rubber Co., South High St., Akron, O., plans to build a tire factory to have a daily output of 2,800 casings here. F. C. Millhoff, general sales mgr.

LOS ANGELES—The Oil Mining Equipment Co., 2026 Santa Fe Ave., will build a group of factory buildings including an 80x547-ft. main building with a 60x150-ft. shed, 20x200-ft. boiler house, etc. Work will be done by day labor.

NATIONAL CITY—The city received bids for the construction of a complete sewer system, including 8 flush tanks, 73 lamp holes and septic tank, from R. H. Downer, 668 Colusa Ave., Berkeley, $94,250; John Engbretsen, 205 McNeece Bldg., San Diego, $110,250; M. McGinnis, San Diego, $116,685.

SAN DIEGO—The Citrus Soap Co., 902 K St., has awarded the contract for the construction of a 4-story, 200x300-ft. soap factory at Union and Market Sts., to the Winter Constr. Co., 2141 Sacramento St., Los Angeles, at $200,000. Noted May 26.

Connecticut

WALLINGFORD—The Interstate Silver Co., 48 State St., Meriden, has awarded the contract for altering the factory and constructing an addition to the boiler house at Plant E, on Center St., to the Immick Co., State St., Meriden. Estimated cost, $250,000.

District of Columbia

WASHINGTON—The General Purchasing Officer of the Panama Canal will receive bids until June 18 for furnishing steel or pig iron, antimony, pig lead, phosphor-tin, silica sand and bituminous enamel, etc.

Illinois

ALTON—The Illinois Glass Co. is having plans prepared for the construction of a glass plant. R. S. Godard, constr. engr.

SANDWICH—The School Bd. will soon award the contract for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, $285,000. J. W. Royer, archt.

Indiana

EVANSVILLE—The Indiana Atomized Fuel Co is building a 1-story, 80x100-ft. plant to reduce coal to an atomized state by means of a chemical process. Estimated cost, from $125,000 to $150,000. B. U. Cain, secy.

Iowa

AURELIA—The Consolidated School Bd. has awarded the general contract for the construction of a 1-story, 80x150-ft. school, to W. J. Zitterell Co., Webster City. Laboratory equipment will be installed in same. Estimated cost, $207,000.

GEORGE—The School Bd. will soon award the contract for the construction of a 2-story, 80x127 ft. high school here. A chemical laboratory will be installed in same. Estimated cost, $90,000. Perkins & McWayne, Sioux Falls, S. D., archts. and engrs.

GREENE—F. L. Stober, Secy. of the School Bd., has awarded the contract for the construction of a 2-story, 66x127-ft. city high school, to the Miller Constr. Co., 502 Black Hawk Bank Bldg., Waterloo. A general chemical laboratory will be installed in same. Estimated cost, $150,000.

ORIENT—J. F. Kingerly, Secy of the Bd. Educ., is having preliminary plans prepared for the construction of a school building. A chemical laboratory will be installed in same. W. Gorden, 319 Hubbell Bldg., Des Moines, archt.

WINFIELD—The city has awarded the contract for the construction of a sewage disposal plant, to the Layton Constr. Co., Muscatine, at $135,000.

Maine

MADISON—The town is having plans prepared for the construction of a 2-story, 82x149-ft. high school here. A chemical laboratory will be installed in same. Harry S. Coombs, Masonic Temple, Lewiston, archt.

Massachusetts

HUDSON—H. M. Hope Engr. Co., archts. and engrs., 185 Devonshire St., Boston, will soon award the contract for the construction of a 5-story, 60x100-ft. factory for the manufacture of rubber goods, for the Apsley Rubber Co., Hudson. Estimated cost, $125,000.

Michigan

ASHLEY—The Bd. Educ. plans to build a 2-story high school. Chemical laboratory equipment will be installed in same. Estimated cost, $200,000. Mrs. M. E. Green, secy. E. M. Wood, 516 Oakland Bldg., Lansing, archt.

DETROIT—Smith, Hinchman & Grylls, archts., Washington Arcade, will soon award the contract for the construction of a 1-story, 79x532-ft. factory addition on Artillery Ave., for the International Metal Stamping Co., Artillery Ave.

PONTIAC—The city has awarded the contract for the water filtration plant, to the Dreher Constr. Co., Flint. Estimated cost, $315,399. Noted April 21.

Minnesota

COLERAINE—A. King, clk., will receive bids until July 15 for the construction of a 2-story, 200x200-ft. high school, for the Bd. Educ. A chemical laboratory will be installed in same. Estimated cost, $350,000. W. T. Bray, 616 Torrey Bldg., Duluth, archt. and engr.

LEWISTON—The Bd. Educ. is having plans prepared for the construction of a 3-story, 60x100-ft. addition to the high and grade school. A chemical laboratory will be installed in same. Estimated cost, $125,000. Croft & Boerner, Palace Bldg., Minneapolis, archts.

WAYZATA—The School Bd will soon award the contract for the construction of a 3-story, 140x150-ft. high school. A chemical laboratory will be installed in same. Estimated cost, $325,000.

Missouri

PILOT GROVE—The School Bd. plans to build a 2-story, 58x70-ft. high school here. A chemical laboratory will be installed in same. Estimated cost, $15,000. H. R. Primmer, Nevada, Mo., archt.

ST. LOUIS—The St. Louis Mill Casting Co., 7701 North Conduit St. has awarded the contract for the construction of a 1-story, 100x484-ft. foundry, at 737-411 Thatcher St., to the Page-Gelmes Constr. Co., Merchants Laclede Bldg. Estimated cost $120,000.

New Jersey

JERSEY CITY—Colgate & Co., 107 Hudson St., has awarded the contract for the construction of a 3-story, 48x82-ft. factory on Morris St., to J. C. Boyce Co., 70 East 45th St., New York City. Estimated cost, $70,000.

KEYPORT—The Whitall Tatum Co., 19 Bartlett St., New York City, has awarded the contract for the construction of a 2-story, 100x200-ft. factory for the manufacture of glassware to H. H. Vaught, Grand Central Terminal, New York City. Estimated cost, $100,000.

NEWARK—Samuel Jones & Co., 21 McCollah St., has awarded the contract for the construction of a 1-story, 50x80-ft. factory addition, etc., to the C. K. Hedde Co., 765 Broad St., at $25,000.

TRENTON—The Perkasian Rubber Corp. has awarded the contract for the construction of three factory buildings on Whitehead Rd., to the Farrell Constr. Co., 55 West 39th St., New York City. Estimated cost, $250,000.

TRENTON—The Van Pottery Co., Parker Ave., has awarded the contract for the construction of a 1-story, 54x68-ft. pottery on Parker Ave., to J. P. Drugan, 184 West State St., at $18,000.

VINELAND—F. H. Bent, engr., 142 West State St., has awarded the contract for the construction of a sewerage system including a septic tank, etc., at the Home for the Feeble Minded, to the New York Sewage Co., 39 East 28th St., New York City, at $13,578. Noted May 19.

New York

NEW YORK—W. Zinsser, West 59th St., has awarded the contract for the construction of a 4-story, 50x50-ft. factory for the manufacture of paint, to Ruggles-Robinson, 331 Madison Ave. Estimated cost, $50,000. Noted May 26.

Ohio

CLEVELAND—The Willard Storage Battery Co., 246 East 131st St., had plans prepared for the construction of a 1-story, 25x260-ft. sheet metal factory.

PROSPECT—The Bd. Educ. plans to build a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, $75,000. O. H. Howard, 8 East Broad St., Columbus, archt.

WHITTEMORE—St. Michael's Roman Catholic Church plans to build a school. A chemical laboratory will be installed in same. Estimated cost, $100,000. Address Parson & O'Meara, Mason Bldg., Ft. Dodge, Ia.

Pennsylvania

FRANKFORD JUNCTION (Philadelphia P. O.)—The Belmont Packing & Rubber Co., 133 North 2nd St., Philadelphia, has awarded the contract for the construction of a 2-story, 120x120-ft. factory to the Hogg Constr. Co., Denchla Bldg., Philadelphia.

South Dakota

ARLINGTON—The Bd. Educ. is having plans prepared for the construction of a 2-story L-shaped grade and high school. A chemical laboratory will be installed in same. Estimated cost, $100,000. Howard Parsons, 600 Builders Exch., Minneapolis, Minn., archt.

Tennessee

MEMPHIS—The Blount Pipe Works, 149 South Front St., plans to construct a 2-story, 50x90-ft. building at 146 Front St. O. E. Hamilton, local engr.

MEMPHIS—The Plough Chemical Co., 122 South 2nd St., is in the market for additional manufacturing equipment. Estimated cost, $50,000.

Virginia

NORFOLK—The Western Electric Co., 302 McKevitt Bldg., plans to build a reinforcement cable plant on a 17-acre site opposite the Navy Yard. F. W. Willard, Western Electric Company's Hawthorne station, Chicago, engr.

Wisconsin

KAUKAUNA—The Thilmany Pulp & Paper Co. will build a [illegible] addition to its plant. C. C. Hoskins, chief engr. Work will be done by day labor.

MILWAUKEE—The Modine Manufacturing & Mfg. Co., 912 So. Lake Bldg., has awarded the contract for the erection of a factory, 80x140-ft. facades on Prospect Pl., to J. M. Cook, 5148 Vel Rose Ave. Estimated cost, $75,000.

RACINE—S. C. Johnson & Son, 1012 16th St., will soon award the contract for the construction of a 4-story, 60x160-ft. warehouse and varnish plant on 16th St. A Guilbert, Robinson Block, archt. Kalbperry Corp., 31 Union Sq., W., New York City, engr.

WEST ALLIS—The Interstate Steel & Mfg. Co., 705 South Pierce St., Milwaukee, will build a 1-story, 80x200-ft. fabricating shop at 47th and Rogers Sts. Work will be done by day labor.

Manitoba

WINNIPEG—The Canadian Government plans to install equipment to sterilize the water supply by ultra violet rays at all the public institutions here. G. Griexson, minister of Pub. Wks.

Ontario

FORT WILLIAM—The Canada Iron Foundries Ltd., has awarded the contract for the construction of a 1-story, 46x80-ft. foundry, to M. H. Bradan, Francis Block. Estimated cost, $20,000.

WINDSOR—The Essex Co. Tuberculosis Sanitarium, c/o Mrs. H. R. Casgrain, pres., plans to build a 2-story sanitarium. Medical equipment for tubercular treatment will be installed in same. Estimated cost. $100,000.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold a regular meeting June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its twelfth semi-annual meeting as follows: June 28 and 29 will be spent in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INSECTICIDE AND DISINFECTANT MANUFACTURERS' ASSOCIATION will hold its midsummer meeting at Boston, July 15 and 16.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

Manufacturers' Catalogs

THE NATIONAL COMPRESSED AIR MACHINERY Co., Los Angeles, Cal., calls attention to Bulletin No. 20, devoted to National class "D" vertical air compressors. Described, together with some illustrations, are compressors as follows: Duplex, vertical balanced construction, permitting of high speeds, high capacity per unit of weight and floor space, and freedom from vibration; three main bearings, carried on the main frame, and fitted with laminated shim brass of 0.002-in. thickness; single acting type, eliminating stuffing boxes, but embodying the National combined piston-cross-head feature, with its attendant pump automatically controlled cylinder lubrication—not an oiler or grease cup on the machine. The valves are a happy medium between the old, heavy, self-destructive poppet type and many of the later delicate, so-called plate types. Inlet and outlet valves are interchangeable. One extra is furnished with each machine, and any broken valve replaced free for two years from shipment of compressor. The dimensions of the extra heavy shaft are published in the bulletin that all may see. Shaft is keyseated on both ends, making it a truly right and left hand machine as shipped. May run in either direction at will. Water jackets completely surround the cylinders and heads, including the discharge valve caps.

New Publications

REFRACTORY MATERIALS AS A FIELD FOR RESEARCH. By Edward W. Washburn. Reprinted from the *Journal* of the American Ceramic Society of January, 1919, vol. 2, No. 1, by the National Research Council, reprint No. 3, price 30c.

NITROGEN: ITS FIXATION, ITS USES IN PEACE AND WAR. By Grinnell Jones. Reprinted from the *Quarterly Journal of Economics*, vol. 34, May, 1920, Harvard University, Cambridge, Mass.

LIST OF REFERENCES ON DYESTUFFS, CHEMISTRY, MANUFACTURE, TRADE. Compiled under the direction of Herman H. B. Meyer. From the Library of Congress, Government Printing Office. Price 15c.

The Inco is the title of the publication of the International Nickel Co., vol. 1, No. 1 of which appeared in February, 1920.

TNT AS A BLASTING EXPLOSIVE. By Charles E. Munroe and Spencer P. Howell. Dept. Circular 94, U. S. Department of Agriculture, Washington, D. C., issued, May, 1920.

THE ELECTRIC FURNACE AS APPLIED TO METALLURGY. Reprinted from the *Transactions* of the American Electrochemical Society, vol. 37, 1920, by Arthur D. Little, Inc., Cambridge, Mass., and known as Bibliographic Series No. 4.

A CHEMICAL SURVEY OF THE NATURAL GASES OF KANSAS AND OKLAHOMA. By H. C. Allen and E. E. Lyder. Engineering Bull. No. 11, published by the University of Kansas, Lawrence, Kan.

ELECTROMETALLURGICAL AND ELECTROCHEMICAL INDUSTRY IN THE STATE OF WASHINGTON. By Charles D. Grier. Engineering Experiment Station Series Bull. No. 5, University of Washington, Seattle, Wash.

AN INVESTIGATION OF THE PROTECTIVE VALUES OF STRUCTURAL STEEL PAINTS. By J. S. Coye. Bull. 54, Good Roads Section, Engineering Experiment Station, Iowa State College of Agriculture and Mechanic Arts, Ames, Iowa.

THE RELATION BETWEEN THE ELASTIC STRENGTHS OF STEEL IN TENSION, COMPRESSION, AND SHEAR. By Fred B. Seely and William J. Putnam. Bull. No. 115, Engineering Experiment Station, University of Illinois, Urbana, Ill. Price 20c.

THE FOREST PRODUCTS LABORATORY, Madison, Wis., has published the following: "The Use of Fluorides in Wood Preservation"; 14 pages, with tables and bibliography; discusses in detail the results of experiments in Europe and America, and shows that sodium fluoride has considerable preservative value. "Automatic Regulation of Humidity in Factories," 4 pages, illustrated; reprint from *Scientific American Monthly*, January, 1920; describes apparatus developed at the Forest Products Laboratory for automatic control of moisture content in wood products during manufacture. "Wood Ashes and Production of Potash," 5 pages, illustrated; reprint from CHEM. & MET., Nov. 12-19, 1919.

THE BUREAU OF FOREIGN AND DOMESTIC COMMERCE has published the Commercial Handbook of China, by Julean Arnold, in two volumes, with a total of 1,100 pages.

STATE AMERICANIZATION. By Fred Clayton Butler. Bull. 1919, No. 77, published by the Bureau of Education, Department of the Interior, Washington, D. C.

COMMUNITY AMERICANIZATION, a handbook for workers. By Fred Clayton Butler. Bull. 1919, No. 76, published by the Bureau of Education, Department of the Interior, Washington, D. C.

U. S. TARIFF COMMISSION PUBLICATION: Tariff Information Series No. 14, The Incandescent Gas-Mantle Industry.

NEW FEDERAL BOARD OF VOCATIONAL EDUCATION PUBLICATIONS: Bull. 45, Job Specifications; Bull. 46, The Turnover of Labor; Bull. 47, Industrial Accidents and Their Prevention.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONSS I: A, The Work on Mineral Resources Done by the U. S. Geological Survey, by Edson S. Bastin and H. D. McCaskey (Mineral Resources of the U. S., 1918, Part I), published March 31, 1920; I: 15, Gold, Silver, Copper, Lead and Zinc in Arizona in 1918, by V. C. Heikes (Mineral Resources of the U. S., 1918, Part I), published Feb. 20, 1920; I: 16, Gold, Silver, Copper, Lead and Zinc in Utah in 1918, by V. C. Heikes (Mineral Resources of the U. S., 1918, Part I), published March 4, 1920; I: 17, Gold, Silver, Copper, Lead and Zinc in California and Oregon in 1918, by Charles G. Yale (Mineral Resources of the U. S., 1918, Part I), published Feb. 24, 1920; I: 18, Gold, Silver, Copper, Lead and Zinc in Idaho and Washington in 1918, by C. N. Gerry (Mineral Resources of the U. S., 1918, Part I), published Feb. 27, 1920; I: 21, Secondary Metals, by J. P. Dunlop (Mineral Resources of the U. S., 1918, Part I), published April 9, 1920; I: 25, Copper in 1917, by B. S. Butler (Mineral Resources of the U. S., 1917, Part I), published March 13, 1920; I: 26, Gold, Silver, Copper, Lead and Zinc in Colorado in 1917, by Charles W. Henderson (Mineral Resources of the U. S., 1917, Part I), published March 1, 1920; II: 18, Potash in 1918, by W. B. Hicks (Mineral Resources of the U. S., 1918, Part II), published March 31, 1920; II: 19, Asphalt and Allied Substances in 1918, by C. C. Osbon (Mineral Resources of the U. S., 1918, Part II), published March 31, 1920; II: 20, Mineral Waters in 1918, by Arthur J. Ellis (Mineral Resources of the U. S., 1918, Part II), published March 19, 1920; II: 21, Architectural Concrete Stone and Concrete Blocks in 1917 and 1918, by G. F. Loughlin (Mineral Resources of the U. S., 1918, Part II), published March 16, 1920; II: 22, Strontium in 1918, by George W. Stose (Mineral Resources of the U. S., 1918, Part II), published March 30, 1920; II: 23, Asbestos in 1918, by J. S. Diller (Mineral Resources of the U. S., 1918, Part II), published March 20, 1920; II: 24, Talc and Soapstone in 1918, by J. S. Diller (Mineral Resources of the U. S., 1918, Part II), published March 29, 1920.

NEW BUREAU OF STANDARDS PUBLICATIONS: Scientific Paper No. 356, Microstructure of Iron and Mild Steel at High Temperatures, by Henry S. Rawdon and Howard Scott, issued March 15, 1920; Scientific Paper No. 367, Turbidity Standard of Water Analysis, by P. V. Wells, issued March 17, 1920; Scientific Paper No. 371, A New Cadmium-Vapor Arc Lamp, by Frederick Bates, issued April 10, 1920; Scientific Paper No. 372, Wave Lengths Longer Than 5,500 A in the Arc Spectra of Seven Elements, by C. C. Kiess and W. F. Meggers, issued May 7, 1920; Scientific Paper No. 375, The Double-Polarization Method for Estimation of Sucrose and the Evaluation of the Clerget Divisor, by Richard F. Jackson and Clara L. Gillis, issued March 30, 1920; Scientific Paper No. 376, Critical Ranges of Some Commercial Nickel Steels, by Howard Scott, issued April 6, 1920; Scientific Paper No. 377, Intercrystalline Brittlesness of Lead, by Henry S. Rawdon, issued April 6, 1920; Tech. Paper No. 155, Cements for Spark-Plug Electrodes, by Homer F. Staley, issued Feb. 21, 1920; Tech. Paper No. 156, Metallographic Features Revealed by the Deep Etching of Steel, by H. S. Rawdon and Samuel Epstein, issued March 19, 1920; Tech. Paper No. 158, A Peculiar Type of Intercrystalline Brittleness of Copper, by Henry S. Rawdon and S. C. Langdon, issued April 10, 1920; Tech. Paper No. 159, Porosity and Volume Changes of Clay Firebricks at Furnace Temperatures, by George A. Loomis, issued April 26, 1920; Tech. Paper No. 161, by W. B. Newkirk, issued April 6, 1920.

And the Mountain Labored And Brought Forth—Harding

HERBERT HOOVER was not nominated for President by the Republicans at Chicago last week. Instead the country was treated to an anticlimax in political affairs the like of which has not been witnessed in a generation. We claim no astuteness as political observers or prophets, but it requires no seventh son of a seventh son or veiled seer to detect the machinations of the Old Guard in determining for the members of a great political party their nominee for the Presidency. It would be to laugh were it not so pitifully tragic. And had better material been lacking, the mediocrity of the successful candidate would not have been so painfully evident as it now is by contrast with the superiority of some of his opponents.

The *dénouement* is the best argument yet produced for some device that will enable the American people to select a President with some consideration for his fitness for the job. HERBERT HOOVER'S candidacy was in effect a protest against the old régime, and the popular support which unquestionably was his throughout the country was a rally to that protest. We need waste no words of denunciation over what was done at Chicago, but we cannot be blind to the need, more insistent than before, of a new type of thinking in national affairs.

No group of engineers or technically trained men would be guilty of such a monstrous farce as was perpetrated at Chicago last week. They do not select an artist to design and build a bridge nor a dispensing druggist to operate a great chemical works; nor would they pick a second-class politician to direct the complex affairs of a great nation. Their training and experience naturally protest against the selection of anyone unfit for his duties.

It is indeed time that the voice of the engineer be heard in public affairs. We know that his methods and policies will not please the orthodox political leader, but we are quite cetain that the results of his labors will be to the advantage of the country. Unless there be something in political life which leads men to forsake the dictates of their best judgment, we believe that engineers would select men with something of the same care and particularity that they now apply to materials of contruction. The same powers of logic and analysis that they now bring to bear on the solution of a scientific problem would be applied in diplomacy and statesmanship; and their previous success in professional work would be a recommendation worth considering.

Somehow the longer we contemplate the Republican national convention, the prouder we are of the conference of engineers in Washington when the Federated American Engineering Societies was formed.

Congressional Acts of Omission

WHATEVER may be one's personal opinion and preference on the Treaty of Peace and the League of Nations, and the merits of the controversy between the President and the Senate, it is impossible to escape the conviction that commerce and industry have suffered because Congress was so embroiled in a political fight that it failed to give attention to the industrial needs of the nation. Legislation of the utmost importance was sidetracked while eloquent Senators paid their respects to members of opposing political parties, with the result that Congress adjourned *sine die* without enacting vital legislation on which a vast amount of time and energy had been spent. The so-called dye bill designed to foster and protect the domestic coal-tar industry was filibustered to death by Senator THOMAS, who apparently is a blind opponent of protection to American industry. It may be that the proponents of the bill were too anxious and too confident, and that their own testimony gave basis for the belief that a monstrous monopoly would be established. And we know how odious an industrial monopoly has been in recent years. It is further evident that the conflict of interest between the makers and users of dyes prevented harmonious support of a tariff program.

All other tariff bills relating to minerals, glass, porcelain, apparatus, etc., died without action.

The water-power bill was passed by both houses of Congress, and those who had worked so insistently for twelve years to secure legislation on this subject hoped that their labors would be rewarded. It was unfortunate, therefore, that the President, for whatever reason, failed to sign the bill before Congress adjourned. Possibly this was due to the fact that the Departments of War, Agriculture and the Interior were concerned with the bill and were unable to approve it for signature in due time. The Attorney-General is reported to have stated informally that the President has ten days following the adjournment of Congress in which to sign bills, but no official pronouncement has yet been made. Water-power development in the United States is therefore delayed for another year or two—a period during which we may expect high prices for coal and labor, and one in which the development of economical power will be most urgent.

The bill to establish the United States Fixed Nitrogen Corporation was, at the last moment, favorably reported to the Senate. This gives it the advantage of a position on the calendar, but the long delay which must ensue in its further consideration, during which time the Government nitrate plants must remain idle, is greatly to be regretted.

The bill to increase the force and salaries in the

Patent Office also died without action. This is greatly to be regretted, because salaries in the Patent Office are woefully inadequate and the service is suffering by the resignation of men who can no longer enjoy the luxury of working for the Government. We are less sympathetic, however, with the other patent bill, authorizing the Federal Trade Commission to accept and administer, for the benefit of the public, inventions, patents and patent rights. Such a bill passed the Senate March 22, and was on the House calendar for consideration. In modified form it was saddled as a rider onto the salaries bill. Whatever may be the merits of this proposal, they seem at first glance to be outweighed by obvious objections.

Practically the only act of Congress in which chemists can take any satisfaction was the passage of the Army reorganization bill, in which provision was made for the retention of the Chemical Warfare Service as a separate unit. This was accomplished after all hope seemed to be lost, and in spite of the unsympathetic attitude of the Secretary of War and the Chief of Staff. That Congress was able to see the light as presented by proponents of the measure is greatly to its credit.

The Relation of Botany to Chemistry

IN A late number of the *Journal* of the Society of Chemical Industry J. B. FARMER called attention to the rather neglected relations between economic botany and chemical industry. He urged a more intense consideration of the subject, and we second the motion.

In a popular article lately published in the *Saturday Evening Post* Dr. HERBERT C. HOOVER called attention to the fact that our leading economic requirement today is to make agriculture produce and thrive. The situation is that unless we grow our own food and clothing we must buy material for these needs abroad, and the obligation to do this will put us in the position in which England and Germany were before the war. We shall be competitive buyers of food and clothing in foreign countries and as one of the earth's industrial nations we shall need to maintain a great navy to keep the best markets open to us, we shall be in constant strife with our neighbors for advantage in this respect and the outlook for living on terms of amity with them will become cloudy. On the other hand, if we produce our own food and raiment, we can manufacture as much as we can find a market for and there will be nothing to hinder us from living in peace and good will toward all and from all. He emphasized, as the greatest hazard to this desired condition, the invasion of agriculture, which has been in process for some time, by industry. If industry draws labor away from the farms, the farms cannot produce.

There are also other sides to the relation of agriculture with industry, and one of these is the needed introduction of engineering into farming. Our land does not produce what it should produce, and if good results are to be obtained this must be at least doubled. It can be done, provided we go about it intelligently; but it will require competent engineers to turn the trick. An example of such development is shown by the great area of former swamp land in western New York which was reclaimed under the brilliant leadership of THEODORE ELY KNOWLTON, of Rochester, a well-known engineer. The results showed increased values, agricultural wealth and more particularly increased production that were materially greater than was anticipated. Given the same wages, most men prefer to work in industry in cities to working on farms in the country. Why is this? Men tend to huddle together rather than to disperse like molecules in a gas. If we apply BOYLE'S law we shall recognize that this decrease in volume is due to increased pressure from without, and it is easy to learn that this pressure is due to a desire for freedom during hours of leisure, to a wish for fixed hours, to a desire for gossip, and to see lights at night, and because women are even more urgent than men in this respect. All these things may be had in industrial farming, and industrial farming is a problem of engineering, in its lay-out. But industrial farming is impossible without better yields, and better yields demand research in botany and biological chemistry and in the physiology of plants. Given a large industrial establishment with enough produce to look out beforehand for markets and distribution, with contented workmen, with control laboratories and research constantly in process, and it can succeed where the single farmer with a hundred and sixty acres of diversified products will fail. It will require thought and education and intelligence and imagination and administrative ability; but what are engineers for if not to supply these very requirements? With botany and chemistry wedded to engineering, industrial farming and abundant yields will become possible. In our number of June 2 we published an article by Dr. MILTON WHITNEY that told clearly how, under proper control, the economical use of fertilizers may be improved. What is needed is the very quality of intelligence that industrial farming can and probably will call to its aid.

Another side to the co-ordination of botany with chemistry is in the furnishing of raw materials for chemical industries. These come only in part from mines. There is a report of certain hybrid trees similar to spruce that grow with great rapidity, maturing within less than half the time of ordinary wild spruce. The meaning of such an achievement to the paper industry is of immense importance—but we have yet to learn of a confirmation of the report or of any excitement in the paper industry over the possibility of such a botanical masterstroke.

The best quality of book and magazine papers may be made economically from bamboo, and bamboo grows in the United States on the mainland and in great abundance in its possessions, but we don't seem to be bothering much about the nature and varieties of the shrub, despite the paper famine.

Occasionally we learn of organic chemical products that heretofore have been synthesized only with the greatest difficulty and at high cost, which are available in large quantities in certain kinds of plants. We don't even know why these substances are found there and we are greatly surprised when we learn it. As soon as we do we repair straightway to the earth-and-sun product for our intermediate material, instead of beginning with benzene or naphthalene, working an interminable time, and then getting only restricted yields. If we knew more about plants we should know where to get many products that are now hard to obtain.

The soil offers us raw materials in perpetuity. Isn't it worth while to see what it has to offer and to look into its capacity to supply us with many things we need? Sometimes botanists bring great gifts. There was CHARLES DARWIN, for instance. He was a botanist.

Minerals Separation Forestalled In Contempt Proceedings

JUDGE BOURQUIN'S decision dismissing the contempt proceedings brought by Minerals Separation, Ltd., against the Butte & Superior Co. appears upon another page. The complainants charged that Butte & Superior was using less than 1 per cent of oil in violation of the Court's injunction.

This decision—in which the complainant, Minerals Separation, Ltd., is "remitted to some one of the familiar methods to secure determination upon the merits of these alleged infringements" and is told that it "cannot be permitted to transfer the controversy from merits to contempt"—is of general interest because it is a check upon the tendency which Minerals Separation, Ltd., has developed to assume proprietorship of all flotation, because of the *result*. This assumption is contrary to the Supreme Court's decision in the Butte & Superior case, in which the court distinctly states that Minerals Separation, Ltd., is entitled to protection on a *process* and not on a *result*.

The decision is of particular interest, coming, as it does, just as an exactly similar attempt is being made to have the Miami Copper Co. declared in contempt.

Elimination Examinations Suit the Mirror Minds

REPORTS from the colleges throughout the country indicate that during the past year students in unprecedented numbers took up the study of chemistry. Everywhere both laboratory facilities and teaching staffs were strained. To meet the situation some institutions immediately enlarged both laboratories and staffs, some gave examinations to eliminate the excess of students, some did both and some did nothing with the result that their educating effectiveness was considerably reduced. Of these four measures, only the first can be approved, the second should not be tolerated, the third may be excused with certain reservations, while the fourth should not be awarded the dignity even of consideration.

The passing of both rigid entrance qualifications and examinations should be required and no larger classes formed than can be efficiently taught. It is altogether a too common practice to allow an excess initial registration and then after a month or so flunking all but the number for whom apparatus can be provided, leaving a lot of men stranded at a critical time. Some institutions are reported to have made as high as 40 per cent reductions this year in chemical courses apparently without a thought of their true obligations.

The reason why the elimination of excess students by means of examination grades alone should not be approved will readily be seen from the following:

A few years ago the dean of a well-known university in looking over the grades found that the examination marks of four Chinese students were suspiciously alike. He immediately sent for their examination papers and upon comparing them found they were so nearly identical that three must be copies of an original. In order to find which ones were the rogues, the Chinese were told that their examination papers had been lost and it would be necessary for them to write them over again. Every precaution was taken to catch any signs of communication among them, but not a trace of cheating was observed. When the second examination had been finished the dean was astonished to find that he had not solved the question, for he had four more identical papers. The perplexity was eventually solved by finding that all four Chinese were honorable copiers, each having memorized the language of their texts.

From their complicated language the Chinese have received an exceptional amount of memory drill, which soon becomes a phenomenal quantity if further exercised in stowing away an American college education. Such a development of memory produces a mirror mind, which reflects all that enters it with ease. In some professions, such as acting, the mirror mind is at a premium, but in the practice of the sciences it may be quite mediocre. Yet the grades received from most any examination possible to devise are to an important extent a function of mirror mindedness. Therefore they should not be a prime factor in determining whether or not a student can profitably use his time studying a science, chemistry at any rate.

In reporting the final grades of Chemistry Y to the professor in charge, a young assistant felt very enthusiastic because every student had received a mark above that required for passing. He was very much upset when his superior not only did not reciprocate, but began scanning the list with a view of getting at least a man or two. Muttering to himself, "This will never do. What will the dean think of this course if I pass everybody?" the professor finally picked out SMITH, who had only a snug margin over the flunking line. Knowing SMITH'S case well, the assistant took up his defense, stating that while SMITH was not as brilliant in expressing himself in an examination as the others, he had worked harder than most of the men in the course and merited passing. In after years SMITH was numbered within the few of that class who made successful use of their chemical training.

It is obvious that if SMITH'S class had been too large to suit stinted college facilities, he would have been one of the first to fall before the elimination examination. Some other standard of sizing up students is needed, and if any are to be eliminated from continuing the chemical courses, it should be the ones who are not putting all their efforts into their work and just get by with the aid of a mirror mind. The young stuttering Demostheneses should not be sacrificed because they lack a nimble tongue at examination time.

Cleaning Up Mexico—With Soap

STATISTICS are proverbially dry and uninteresting, and even the curious would scarcely look for anything startling in figures showing domestic exports of soap from the United States. But we submit that there is food for thought in the fact that in April of this year of grace we sent 2,352,313 pounds of soap to Mexico. This was one-fourth of our total exports of soap. Visions of the great unwashed should fade before such evidence of cleanliness, for it may safely be assumed that the commodity is used in processes of ablution. And if it be true that cleanliness holds among the virtues the exalted position usually ascribed to it, our southern neighbors are perhaps more godly than we thought. Here are possibilities, maybe, undreamed of by statesmen, soldiers and missionaries. What a simple process of regeneration and conversion—moral and spiritual! How delightful the transformation through unction applied to body and soul; superior to bullets and less distressing than gas. The chemist may yet be called upon to clean up Mexico.

Western Chemical & Metallurgical Field

Liberty Potash Co. in Receiver's Hands

The Liberty Potash Co., which was organized by Salt Lake City interests for the extraction of potash from leucite in Wyoming, is in the hands of the Bankers Trust Co. as receiver. Efforts are now being made to re-finance the company with the intention of putting the plant in operation again. It is reported that about $800,000 was raised originally for the construction of the plant at Green River, Wyo., and that subsequently an indebtedness of about $300,000 was contracted in its operation, making a total of $1,100,000 represented in the venture.

The lack of adequate technical direction in the design and operation of the plant is assigned as one of the reasons for the failure of the company. Potash in the form of chloride equivalent to 35 per cent K_2O was produced to the extent of about twenty-one carloads, and proved to be an excellent material for fertilizer, and it is still believed that the process can be operated with sufficient skill and economy to make this product at a profit under present market conditions. In brief the process consists in volatilizing KCl by calcining leucite with lime rock and sodium chloride in the ratio 60: 30: 10, and catching the volatilized chloride in bags.

Photographic Chemicals Being Produced on the Pacific Coast

The production of the so-called "modern" photographic developers in this country is a recent achievement and marks a step in the advance toward our chemical independence. Previous to 1915, for instance, all of the "metol" used by American photographers was imported, being produced almost entirely in Germany, a relatively small portion being made in France. When the importation of this largely used developer was cut off, "serchol," which was manufactured in England, was offered and used extensively as a substitute.

It seems to be the consensus of opinion that "metol" of the highest purity has advantages not possessed by other developers, and the production of this chemical was undertaken by many chemists and chemical manufacturers during the last four years, but until recently without great success. A very satisfactory grade of metol is now being made by the American Chemical Co., of San Francisco, and is largely used by the motion-picture studios near Los Angeles as well as being supplied to the general trade. The process by which it is made was developed by W. J. Van Sicklen, and he has also been successful in the production of hydroquinone and other photographic chemicals, together with a few allied pharmaceuticals.

Until recently practically all of the heavier photographic chemicals used in the West have been made in the East. The Arthur R. Maas Chemical Co., of Los Angeles, has developed a process for the manufacture of and is now producing considerable quantities of "hypo" and sodium sulphite.

The "metol" and "hypo" are being produced from raw materials obtained locally or else imported directly from the Orient to Pacific Coast ports. This indicates that the chemical industry in this section of the country has advanced to an extent sufficient to supply materials needed in the manufacture of the more refined chemical products.

Fuel Oil Becoming Scarce and Expensive

Failure of existing and prospective oil fields to maintain equality of production to the consumption of petroleum products has been predicted by reliable authorities. The truth of this is already becoming apparent and the situation is acute in certain parts of the country. In March of this year the Standard Oil Co. (California) increased the price of fuel oil 25c. per bbl. and of gasoline 2c. per gal., at the same time paying an additional 25c. per bbl. for crude oil at the wells. In announcing this advance the company stated that an increase in prices was the only known and tried means at its disposal that would bring about an increased production of crude oil, prevent the shipment of fuel oil and gasoline to competitive markets and at the same time restrain demand. In January, 1920, the output of California's refineries amounted to about one-tenth of the gasoline and one-quarter of the fuel-oil production of the United States. It is but a question of time until conditions such as now exist in California will be reflected throughout the country and ultimately result in becoming a question of national importance, since there is now lacking an adequate means of effectively combating the situation.

Power derived from fuel is becoming increasingly expensive and the consumer of power so obtained must face an uncertainty in the supply, this being particularly true of that from fuel oil. Recent experiences, the result of strikes affecting transportation and the production of fuels, have brought this forcibly to attention. In establishing new industries, the source of power and the effect of increased consumption on the future costs are factors which must be given consideration; more particularly will increased power costs adversely affect electrochemical industries.

The Resources of Colorado

In a recent address before the Denver Commercial Club, Charles C. Gates showed that the state possesses 1,000,000 undeveloped hydro-electric hp. according to the U. S. Geological Survey, 383,000,000,000 tons of unmined coal and vast oil shale deposits which have been shown to hold seventeen times as much oil as taken out in the wells of the United States since 1857.

With charts prepared by the Denver Gas & Electric Co., he demonstrated that Denver's power is supplied at cheaper cost than that prevailing in the Atlantic States, Eastern Central States, and Western cities except Los Angeles, which has the lowest power costs in the country. Aside from the production of the metals, Colorado offers many possibilities to the chemically-controlled industry.

Copper and Magnetite in Copper Smelter Slags—I

Chemical and Microscopic Examination of a Series of Representative Slags, Showing How Copper Losses Occur, the Relation of Magnetite to Copper Loss, the Behavior of Converter Slags in Reverberatory Furnaces and Suggestions for Reducing Copper Slag Losses

BY CHARLES G. MAIER AND G. D. VAN ARSDALE

TODAY'S urgent necessity for the maximum economy of operation of all basic industries should renew the interest of metallurgists in smelter losses. Maximum production being no longer an immediate *sine qua non*, a critical examination of even those losses which ordinarily are deemed at a minimum is entirely justified.

In considering the problem of metal loss in copper smelter slags, two aspects are pre-eminent: How far is satisfaction with a conventional average 0.3 or 0.4 per cent copper loss in reverberatory or blast-furnace slags justifiable? and, What should be done with secondaries? In attempting an answer to these or similar questions, one may search technical files in vain for such fundamental information as the actual condition in which copper exists in slags, or even as to just what happens when converter slags are poured into reverberatories.

Such information as is available is usually the result of personal experience in the operation of furnaces. Thus one person may postulate that, because he has had trouble with unsettled prills of matte in slag, such constitute the serious source of loss, if not its totality, while another who has had matte-clean slags suspects only the presence of oxides in the silicate portion of the melt, and still others suspect, but do not explain, some relationship between magnetite in slags and copper loss. All are correct in degree, but a comprehensive theory to account for empirical facts, and based on close examination of the actual materials themselves, is lacking and would seem to be highly desired.

In a previous article[1] the authors have attempted to show that while chemical methods of attack, when used alone, are inadequate for the development of any comprehensive theory, a combination of chemical and microscopic methods seems capable of furnishing much new and interesting information. After a brief discussion of previously published material, the article mentioned points out the manner in which the copper constituents and the magnetite in reverberatory, blast-furnace and converter slags may be classified, and presents experimental evidence for distinguishing the various forms of inclusions, etc.

While this previous work was entirely confined to samples representative of the practice at that time in various Phelps Dodge Corporation branches, opportunity has since been had to extend the examination to various other slags produced at copper matte-smelting works, and moreover work has been done on samples from reverberatories taken during the admixture of converter slag. This latter work in particular throws much light on previously obscure relationships between copper loss and magnetite or ferric iron, and has led to the attainment of a mental picture of various phases of matte smelting which should be of general interest.

[1] ENG. AND MIN. J., May 10, 1919, vol. 107, p. 815; abstracted in CHEM. & MET. ENG., vol. 21, pp. 46 and 61.

RESUMÉ OF PREVIOUS WORK BY THE AUTHORS

Inasmuch as the discussion of the work described in the present article is very closely related to previous results, the following brief summary of the latter is given.

It was found that in the reverberatory and blast-furnace slags examined there was present but one microscopically visible form of copper—namely, a matte *residue*. Matte on solidification seems to be primarily a two-constituent material, containing an iron sulphide constituent saturated with copper sulphide, and a copper sulphide constituent saturated with iron sulphide or metallic copper. The latter phase is equivalent to white metal and it is this part of the original matte which is visibly distinguishable as pellet-like inclusions in the slag. Quantitative chemical methods, devised to determine the amount of these pellets, accounted for only a part of the total copper, the difference being copper dissolved in the silicate portion of the slag. The amount dissolved was found to be approximately constant and between 0.15 and 0.20 per cent. Further chemical and microscopic evidence indicated the dissolved content to be present as sulphide. The facts that the visible pellets of copper sulphide were only rarely matte and usually white metal, the disappearance of the iron sulphide constituent being accompanied by the presence of gas bubbles, tending to keep the pellet afloat, were taken to indicate chemical reactivity with the formation of sulphur dioxide. The reaction was concluded to involve the oxidation of iron sulphide, or possibly copper sulphide by ferric iron.

In converter slag a larger portion of the copper content was found to be the pellet form of white metal, although the dissolved content was in these slags varied, averaging from 0.1 to 0.5 per cent copper.

Of great importance in relation to our present work was the classification of slags according to the magnetite crystals occurring therein, as follows:

1. Slags without visible magnetite crystals typical of blast-furnace or extremely rapidly chilled reverberatory slags.

2. Slags showing magnetite crystals formed during solidification, typical of usual reverberatory slags.

3. Slags with well-formed, clean-cut and large magnetite crystals, formed during the molten condition, typical of converter slags.

EFFECT OF ADDING CONVERTER SLAGS TO REVERBERATORIES

In March and April, 1919, a series of reverberatory slag samples was taken at the Copper Queen smelter, representing the condition of slag at time intervals, before and after the addition of molten converter slag. The microscopic and chemical examination of these samples in the light of previous work on the classifica-

tion of copper losses and magnetite crystal forms has led to some interesting results.

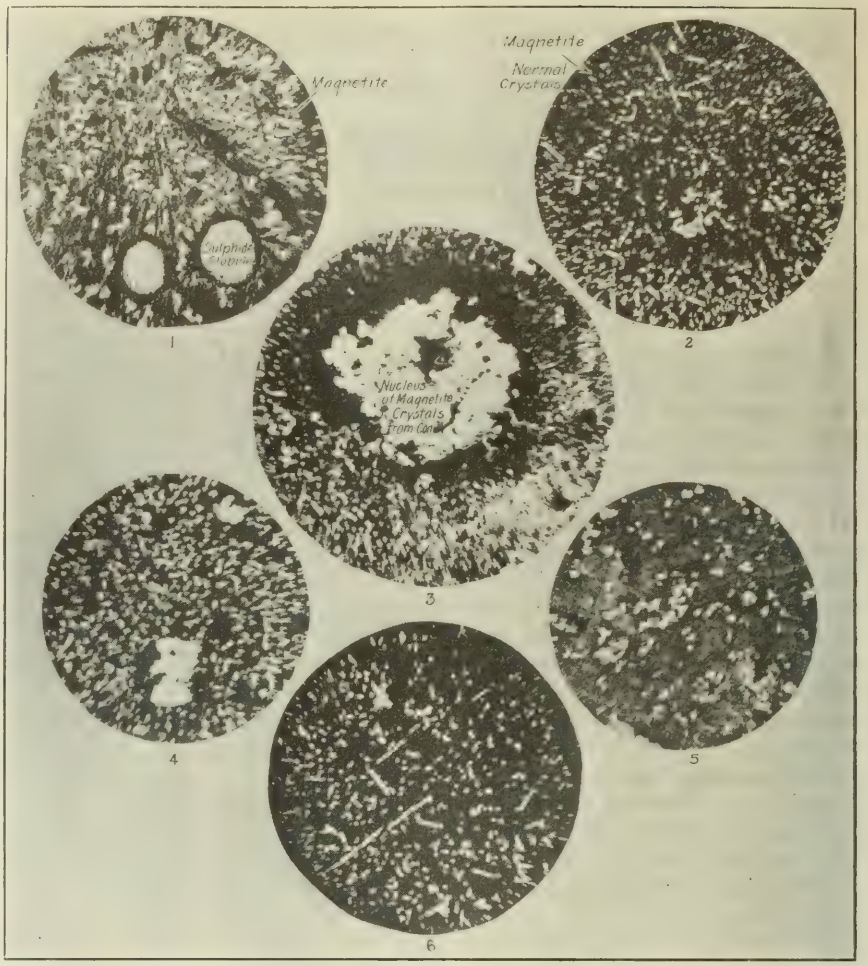
A cursory microscopic examination of these samples, which were taken at the time of converter-slag pour, and at lapses of ten, twenty, thirty and forty minutes, shows no unusual condition as far as copper content is concerned, except for the presence of some metallic inclusions (which will be discussed below). Consequently the chemical method for distinguishing between the total dissolved and pellet copper (silver nitrate method described in previous article) was considered a satisfactory criterion for the chemical determination of the effect of the addition of converter slag to reverberatories. Table I shows the results obtained.

The effect of the admixture on the copper content of the *mixed* slag is clearly indicated by the first row of figures, showing that the total copper content increases unmistakably. The increase is completely due, however, to an increase in the sulphide copper globule content. The third row of figures, giving the dissolved copper, shows practical constancy for the entire period of the test and even samples taken a month later, shown in the second part of the table, have an average dissolved copper content extremely close to the original.

If one assumes 0.06 per cent copper, as shown in the table, to be the normal globule content before the addition of converter slag, the last row shows an excess amount of globules, due to the addition, and of about the same order of magnitude as the normal, and even though the total amount of copper represented be small, the results seem to warrant the conclusion that the addition of converter slag was the cause of a definite increase in suspension not to be accounted for by the small percentage of secondary slag added.

There is no *a priori* reason discernible why the dissolved copper content of reverberatory slags should be changed by the addition of moderate amounts of converter slag, which affect only to small degree the composition and temperature of the melt. Theory and observation are in accord here. For the suspended globules, however, if previous theories of the reaction of sulphides of iron with ferric iron are correct, there should be found in the iron content of the slag the explanation of the increase of suspended copper noted in Table I.

The flotation effect due to the reaction of ferric iron with sulphides to form sulphur dioxide gas should be related to the ferric iron content of the slag. Microscopically it is possible that only a part of the ferric iron is visible as magnetite. Moreover, the magnetite, as revealed, is so variable as to render quantitative results from microscopic examination impractical, so that a chemical method of correlation was sought. The method finally chosen for the chemical determination of ferric iron in these slags was that of disintegration with hydrofluoric acid in the presence of an atmosphere of carbon dioxide. There are objections to this method, but details of procedure and the justification of the method for the present purpose will be found in the appendix.



FIGS. 1 TO 6. MICROSECTIONS OF SLAGS FROM COPPER QUEEN SMELTER
Fig. 1. Converter slag. Fig. 2. Reverberatory slag before addition. Fig. 3. Reverberatory slag, 10 min. later. Fig. 4. Reverberatory slag, 20 min. later. Fig. 5. Reverberatory slag, 30 min. later. Fig. 6. Reverberatory slag, 40 min. later. All microphotographs originally at 75 ×, reproduced at 40 ×. HF etching.

The results obtained are of first interest, as will be evident from the examination of Table II. As expected, there is a definite increase in the ferric iron content of the reverberatory slag after the addition of converter. Whether or not the total ferric iron content should be considered as magnetite is scarcely pertinent for the present discussion, for since magnetite is re-

†Based on assumption of complete crystallization of ferric iron as such, probably unwarranted, but given for comparison with photograph.
‡A.D. = average deviation from mean.

active with sulphides, as proved by the appended photomicrographs, the total ferric iron is the real deciding factor in the suspension of sulphide globules.

Qualitatively there can be no doubt that an increase of ferric iron in slag is closely related to increased suspension, the third and fifth rows of figures in Table II indicating conclusively the coincidence of an increase of suspension with an increase of ferric iron.

That this relationship is quantitative as far as the accuracy of chemical determination enables one to judge is indicated by the figures of the last row. If the suspension of sulphide globules were strictly proportional to the ferric iron content

$$\text{Suspended Cu} \propto \text{Fe}'''$$

then

$$\frac{\text{Suspended Cu}}{\text{Fe}'''} = K$$

where K is a constant numerical ratio. This figure is the one given in the last row, and while these numbers do not show absolute constancy, the variation observed, indicated by the average deviation from the mean value, is approximately 15 per cent. Since the figures involve the determination of an amount of copper of the order of magnitude of 0.1 per cent, this deviation corresponds to an original error of 0.015 per cent copper, which is just about the limit of accuracy of the determination made, and consequently one is warranted in concluding that numerical proportionality exists between suspended copper and ferric iron in these tests.

From the microscopic point of view the above conclusions regarding the relationship of sulphide inclusions in slags to ferric iron is confirmed by the behavior with magnetite which may be actually observed upon examination of polished sec-

tions. Figs. 1 to 6 show pictures of the series of samples taken from 0 to 40 minutes after the addition of converter slag, which were taken at low magnification, and which serve more as an indication of the distribution of magnetite than as a true basis of comparison of its amount. The distribution is sufficiently uniform to serve as a quantitative guide without the use of an excessive number of observations. There are some points, however, of considerable interest. Compare, for example, the normal size of magnetite crystals (converter slag) in Fig. 1 with the normal size in Fig. 2 (reverberatory slag without the addition of converter), and it is apparent that the normal magnetite in reverberatory slag due to crystallization on solidification is considerably smaller in size than that occurring in the normal converter slag where crystallization takes place in a liquid medium. The fact that large crystals of magnetite, exactly similar in appearance to those which previous work has shown to exist in the fluid condition of converter slag, are found in the reverberatory after admixture can be taken to indicate that these particular crystals are the identical ones which existed in the liquid converter slag upon addition to the reverberatory. Furthermore, when after ten minutes' time from the addition large nuclei of highly magnetitiferous slag are seen in the reverberatory sample (Fig. 3), it is an obvious step to conclude that this condition represents the primary step in the assimilation of the converter slag by the reverberatory.

These agglomerates of magnetite crystals disappear with time, confirming the idea of some mode of disintegration of the magnetite other than silicate fluxing.

Fig. 13. Converter slag. Fig. 14. Reverberatory slag before addition. Fig. 15. Reverberatory slag, 10 min. later. Fig. 16. Reverberatory slag, 20 min. later. Fig. 17. Reverberatory slag, 30 min. later. Fig. 18. Reverberatory slag, 40 min. later. All microphotographs originally at 1000 ×, reproduced at 550 ×. HF etching. "P" marks magnetite crystals from converter slag.

as this would require gradual diminution in size of individual crystals. There is evidence, discussed below, that there is considerable tendency for magnetite crystals, when present in fused slag, to settle rather rapidly to the bottom, and the fact of these nuclei remaining suspended indicates the manner in which converter slag is taken up by the reverberatory. There would seem to be no reason for the coherence of these magnetite crystals except through the medium of some surface tension effect in the fused slag. It is a well-known fact that any magnetic phenomena which these crystals might show disappear at a relatively low temperature. The action taking place is, then, first of all, upon addition of fused converter slag containing magnetite crystals to the fused reverberatory slag, the silicate portion of the converter slag is dissolved away into the silicates of the reverberatory, leaving magnetite crystals and numerous sulphide copper globules which were originally present to the extent of several per cent. It will be shown later that copper sulphide in the molten state wets the surface of magnetite crystals, and consequently each original sulphide globule attaches to itself any magnetite crystals with which it may come in contact. There is exact analogy here with the manner in which sulphide minerals attach themselves to oil drops in an aqueous pulp, magnetite taking the place of mineral and fused sulphides that of the oil. According to previous work, sulphur dioxide should be the result of chemical reactions involved in such contact, and accordingly there is to be seen a central gas cavity in Fig. 3. This gas has buoyed up the nucleus and the reactivity is obviously the reason for its continuous suspension in the liquid slag.

Figs. 7 to 12, of specimens similar to Figs. 1 to 6, but at twice the magnification, show somewhat more clearly the difference in the size of the magnetite crys-

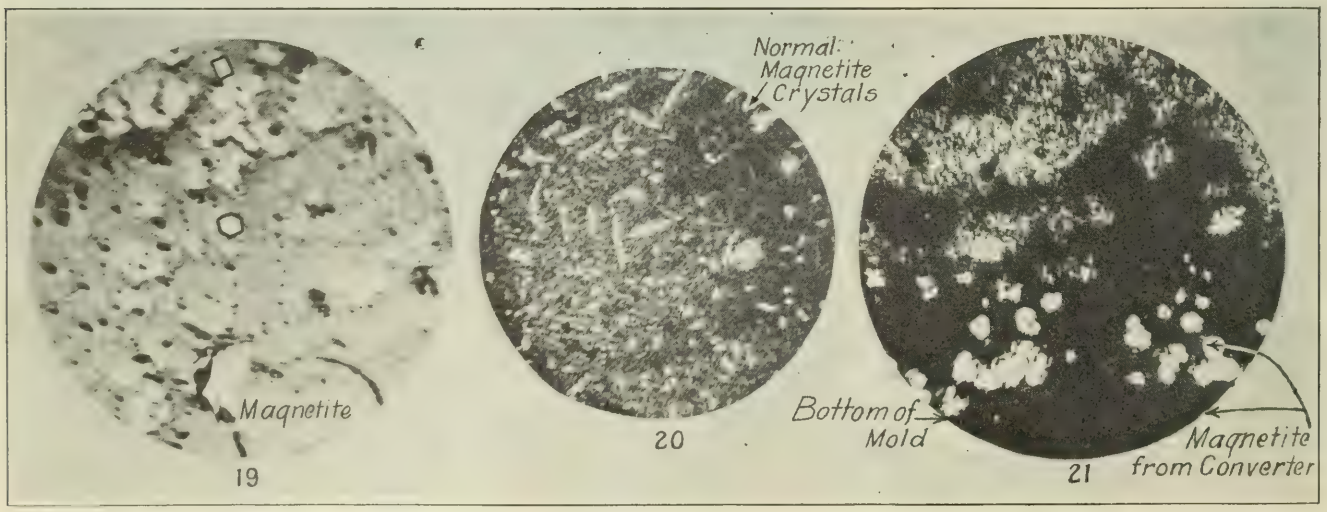

FIG. 19

tals from the two sources originating either in the converter slag or in the normal crystallization of the reverberatory slag on cooling. Again, the crystals in Fig. 7 (converter slag) as compared to those in the unmixed reverberatory (Fig. 8) are seen to be several times as large. In Fig. 9, ten minutes after admixture, not having accidentally struck a position on the slag showing a nucleus, there are visible only occasional large magnetite crystals which had their origin in the converter. These have been designated by the letter *P*. A necessary consequence of the reactivity between magnetite and sulphide inclusions would be the disintegration of the former crystals, and in Figs. 10 and 11 there is apparent a beginning of such action, even though the total outline has not appreciably changed. It is interesting to note, in confirmation of the previous statements, that in Fig. 11 the difference in structure in the silicate phase is visible in the vicinity of the nucleus. As usual, after forty minutes the greater part of the large magnetite crystals have disappeared, and there remains only the normal magnetite crystallization characteristic of unmixed reverberatory slag.

Copper Inclusions in Magnetite

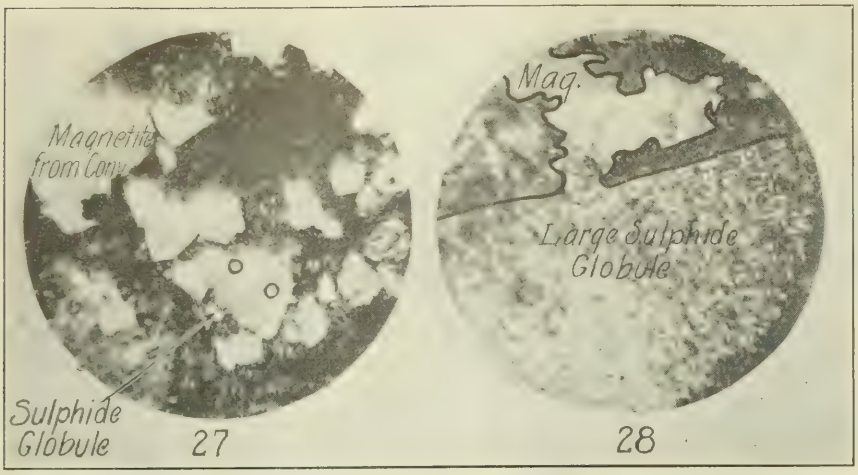
The inclusion of metallic copper in magnetite crystals, heretofore never observed, so far as is known, is a matter of considerable significance and is plainly shown in Figs. 12 to 18. These pictures were taken at a very high magnification (originally 1,000 diameters) and emphasize anew the marked difference in size and structure between the crytals from the two sources. Their especial interest, however, lies in the fact that not only do they show the above-mentioned inclusions in large magnetite crystals, but also show crystal skeletons of originally large crystals whose sides or interiors have been disintegrated because of chemical fluxing action (effect of sulphides!).

Fig. 13 shows a very large and well formed magnetite crystal present in converter slag, and enables us to distinguish two types of inclusion. The large dark spots are gas cavities or at least unfilled holes in the magnetite crystal and their perfectly spherical form would seem to indicate the action of chemical disintegration after the formation of a large perfect crystal had taken place rather than an original cavity due to imperfect crystallization.

The lighter poorly defined inclusions are metallic copper, recognizable as such by the color on visual observation and by the deposition of silver crystals on etching with dilute silver nitrate solution. This phenomenon of copper inclusion may account for the variation on dissolved copper content observed with converter slags when tested by the silver nitrate method, inasmuch as these inclusions are extremely minute and would certainly not be freed by grinding through 100-mesh screens.

The magnetite crystals of Fig. 14, unmixed reverberatory slag, are much smaller and seem not to contain inclusions. If inclusions do occur they must be of little relative significance as far as the copper content of the slag is concerned, inasmuch as no such inclusions are apparent at 1,000 diameters magnification.

Figs. 15 and 16, photographs taken on samples ten and twenty minutes after admixture, show, in contrast to the above, characteristically large magnetite crystals and, of especial interest, also show metallic inclusions. Since the amount of copper in the original converter slag represented by such inclusions in crystals can certainly not be greater than the total dissolved copper—that is to say, approximately 0.5 per cent—it must be



FIGS. 27 AND 28. DIRECT REACTIVITY OF SULPHIDE UPON MAGNETITE
Fig. 27. Reverberatory slag, 20 min. after addition. Fig. 28. Converter slag. Both 1000 ×, reproduced at 500 ×. HF etching.

true that in mixed slags containing 10 per cent or less of converter slag, the effect of such inclusions does not involve significant quantities. At least some portion of metallic inclusions would be shown up as globule content by the silver nitrate method. It is important that these inclusions not observed in normal reverberatory slag are apparently characteristic of the converter and their presence in this mixed slag seems to furnish still further conviction as to the source of the crystals in which they occur.

Of even greater importance in regard to a possible rational explanation of the relationship between copper and magnetite in these slags is the second significant fact that magnetite crystals in the later pictures (see also Figs. 22 and 23) and particularly in Fig. 18 show ragged edges and fragments of originally rather large magnetite inclusions. Inasmuch as such fragmentary crystals are not usual in the converter slag itself where the predominant sulphide constituent is high grade, characteristic of white metal, it seems warrantable to assume that the corrosive action is chiefly due to the iron sulphide portions of these reverberatory slags. This is further confirmation of our previous theory concerning the primary disappearance of the iron sulphide constituent in suspended globules.

Gravitational Settling

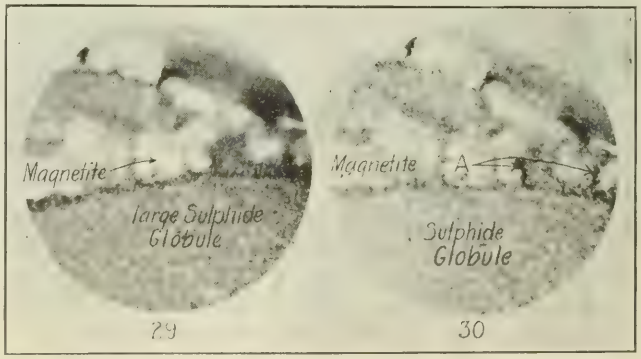
The separation of magnetite from fused slag by gravitational settling is a matter of considerable importance with respect to previous conclusions. It is true that as microscopically apparent on the usual specimen the number of large magnetite crystals characteristic of the converter is less than might be expected from the percentage admixture, but Figs. 19 to 21 show the explanation for this fact and furnish contributory evidence toward the theoretical relationships of sulphur elimination during and after matte smelting. Fig. 19 of converter slag has had two crystals outlined in ink to indicate the average size. Fig. 20, taken near the center of the mold as cast for sampling, shows only minute crystals characteristic of those normally found on solidification and lying in straight rows which indicate definitely their formation during this period. The last picture, Fig. 21, taken near the bottom of the mold, as indicated by the curved line in the margin, shows the number of magnetite crystals of the same size as those in the top section of converter slag. These crystals have settled to the bottom of the mold previous to the act of solidification.

Having shown in previous work the possibility of the reactivity of magnetite and sulphides, the mechanism for the disappearance of the larger magnetite crystals present because of the addition of converter slag can be easily imagined. Any crystal growing to considerable size during some molten condition, because of local oxidizing conditions in the melt, or when added as a large originally well-formed crystal through the medium of converter slag, becomes of a size to insure practically unhindered settling (compare Stokes' law, velocity varies as the square of the radius), rapidly comes in contact with the matte at the bottom of the melt and since it is wet by this phase is subject to rapid disintegration, quite in conformity to the action observed in many micrographs.

The reaction producing metallic copper by contact between magnetite and sulphides may be classified as to whether these sulphides be dissolved or present as suspended inclusions in the slag. In substantiation of the theory to be developed later regarding the correlation of magnetite and copper loss, it is desirable to show that the disintegration of the magnetite crystals is primarily due to reaction with sulphides rather than silicate fluxing. Figs. 24 to 26 show photographs taken to illustrate this point. Owing to the limitations of monochromatic reproduction the points of interest have been emphasized by artificial means. The first picture (Fig. 24) contains a typical group of corroded magnetite crystals. On the original, metallic copper inclusions were easily recognizable, located about the corroded crystal in such a manner as to leave no doubt that they were reaction products. In the absence of excess iron sulphide, the copper sulphide has continued to react with the magnetite, and since no pellets are visible it is probable that this copper sulphide was in the dissolved form.

Fig. 25 is from a photograph taken after treatment of the polished slide shown in Fig. 24, by an etching solution of silver nitrate, thus showing up copper inclusions by means of the bright spots of silver formed thereon.

While Figs. 24 to 26 were taken to show the reaction



FIGS. 29 AND 30. SURFACE TENSION EFFECTS IN SLAG
Fig. 29. Converter slag photographed under yellow monochromatic light. Fig. 30. Converter slag photographed under blue monochromatic light, showing copper in black spots. Both 1000 ×, reproduced at 500 ×. HF etching.

of dissolved copper sulphide with magnetite, the direct reactivity with globules of sulphide is a matter of some importance and is well illustrated by Figs. 27 and 28. Fig. 27 is a particularly good illustration of the reaction. The chief point of interest is the central magnetite crystal with the treelike growth in it. The small semicircular globule at the bottom of the large central magnetite crystal is the remains of a sulphide pellet, and the treelike growth is the path of the lines of penetration of the reaction. The minute globules at the end of the growth are appropriately enough the fruit of the reaction—that is to say, metallic copper.

Fig. 28 shows a much larger sulphide inclusion and the manner in which upon contact with magnetite the sulphide phase pours out of its spherical form to engulf and disintegrate the crystal. The ink lines indicate the extent of the engulfing action and serve to separate the silicate portion of the slag from the sulphide globule and its burden of attached reacting magnetite.

The matter of surface tension relationships between magnetite crystals and sulphide pellets has been mentioned above and Figs. 29 and 30 show photographs taken with the purpose of exhibiting this action. Metallic copper resulting therefrom is also apparent. The photographs have been made more clear by ink lines showing the outline of the constituents as well as by the use of color screens for contrast purposes in photography.

If magnetite were not wet by sulphide globules the reaction which is the source of the flotation of copper-bearing pellets could not take place so readily, and consequently it seems not impossible that some suitable addition agent might be found which when added to the fused slag would alter the surface tension effects in a manner similar to certain flotation poisons which have been noted by various observers in aqueous flotation pulps. If such agents could be found to prevent the wetting of the magnetite, there is no doubt that a considerable portion of the sulphide globule copper loss might be eliminated, since the elimination of the gas due to reaction would permit much improved settling.

(Part II will be published in a subsequent issue.)

Papers on Enameling Before the Chicago Section, American Ceramic Society

The Chicago Section of the American Ceramic Society met at a dinner at the City Club, Chicago, on Friday evening, May 21. In addition to the business program two papers were presented in connection with the enameling industry, the first of which, by L. H. Menne, was entitled "Enameling of Cast Iron."

Enameling of Cast Iron

The first thing to consider in the enameling of a cast-iron piece is its shape. This must be uniform and free from heavy spots and sharp edges. The metal must be a soft open-grain iron with a 2½ to 3 per cent silicon content and about 0.5 per cent manganese. Sulphur must be low.

Care must be taken in molding that the sand is neither too fine nor too coarse in order to obtain an open-grain surface. No facing must be used on the mold. In pouring the iron the metal must not be too hot, as then a film of scale and sand on the cold casting will make it impossible to produce a smooth enameled surface. It is better to cool the metal slowly in the mold in order to give an annealing effect and to prevent cracking of the casting during enameling.

Castings should not be milled before enameling, as this usually produces a too close-grained surface for best results. When necessary to do any finishing the castings must be pickled and sand blasted afterward. The enameling operation should be undertaken shortly after the sand blasting, but if castings have been stored a considerable time all traces of rust must be carefully removed.

Enameling is usually done in a gas-fired open-muffle furnace, the sides of the furnace being high enough to protect the ware from direct flame. The temperature should be from 1,500 to 1,600 deg. F. The slush coat is usually prepared in pans in the muffle furnace, but in large plants a special melter is used for this purpose. The enamel itself consists of quartz, feldspar, borax and sometimes lead, manganese dioxide and cobalt oxide. The mixture is sintered in the muffle furnace for about 2 hr., dropped in water, broken up or allowed to cool in the pan, as the case may be, crushed and then milled.

The cover coat consists of silica, alumina, fluxes and opacifying materials which are smelted, run into water, dried and ground in porcelain-lined mills with porcelain balls. No flint pebbles should be used for dry grinding.

Crazing of the cover coat can be regulated in the mill by adding clay, tin oxide or zinc oxide. It can also be avoided by adding from 3 to 5 per cent of silica in the form of quartz without disturbing any of the other ingredients.

Preparation of Steel for Enameling

L. G. Whitford, of the Benjamin Electric & Manufacturing Co., made a short talk on the preparation of steel for enameling, a brief summary of which follows.

Many enameling shops receive the forms for enameling from outside shops. In such cases the enamel shop should always be sure that an order is made up from one and only one gage of steel, or much annoyance and loss will be experienced when the burning operation is performed.

As a preliminary, grease and oil are first removed by burning them off in a furnace or immersing the form in a chemical bath. If the piece is to be burned it is first usually sprinkled with hydrochloric acid and held in the furnace until the piece is red hot. When a chemical bath is used, the material passes from the acid tank to a water tank, where it is rinsed and sponged by hand to remove the carbon film which remains on the surface after pickling. It is then passed into a neutralizing tank for a few minutes. Soda ash and caustic solutions are most commonly employed for this operation, one-tenth normal solution giving very good results. It then passes from the neutralizer tank to a drying room which is heated to 250 deg. F.

The most efficient cleaning solutions on the market consist of mixtures of caustic soda, soda ash, borax, trisodium phosphate, sodium chloride, rosin and soap. The action of these cleaning solutions is purely physical except in the saponification of the small amounts of animal or vegetable oils that might be present in some cases, cutting the oil away from the surface and emulsifying it. The bath is maintained at boiling or just below.

Selenium and Tellurium

By Victor Lenher*

A RECENT survey made by the Committee of the National Research Council on the uses of selenium and tellurium has shown that the electrolytic copper refining plants in this country, without making any material addition to their plants, can furnish approximately 300,000 lb. of selenium and about 125,000 lb. of tellurium per year. The uses of these elements in quantity are nil. They have a few minor uses. During the war selenium was used in considerable quantity for the decolorization of glass during the shortage of manganese. When the commercial ocean traffic was resumed and manganese was again brought to this country, the demand for selenium by glass companies dropped to practically nothing.

Small amounts of selenium are used in the manufacture of the selenium cell, which is unique in its action toward light. The conductivity of selenium varies so greatly in light and in darkness that this property of its conductivity varying directly proportional to the intensity of the source of light has found several industrial applications in the development of the selenium cell. This selenium cell has been used at various times for automatically turning off city gas lights at daybreak. It has been used to light and to extinguish the lights in light buoys, in army signaling of various kinds based on the heliograph principle, in the wireless telephone, and it has been used by the French as a control in such chemical processes as the contact sulphuric acid.

Metallic tellurium has not yet been found to have any practical applications of even minor importance.

Possible Uses for Selenium and Tellurium

Various possible uses for these elements have been suggested, but a considerable amount of research is desirable. For example: The use of either of the elements in the iron or steel industry. The field of organic medicinals with these elements has barely been touched. The physiological action in the derivatives similar to sulphur and selenium might well be studied. No experiments are recorded on the use of the chlorides or bromides of these elements as acclerators in the rubber industry, nor has the field of synthetic dyestuffs been studied carefully.

An address wes recently given by the writer at the St. Louis meeting of the American Chemical Society, suggesting a number of possibilities for the use of selenium oxychloride as a laboratory and research reagent. If this kind of chemistry can be developed by one new derivative of selenium, it is interesting to contemplate future possibilities in further researches with these elements.

The Engineering Division of the National Research Council has created a sub-committee on the uses of selenium and tellurium, consisting of Arthur E. Hall, chairman; H. G. Greenwood, Victor Lenher, O. C. Ralston, E. W. Rouse, S. Skowronski and A. W. Smith. This committee has been working in close contact with the Raritan Copper Works, Perth Amboy, N. J.; the United States Metals Refining Co., Chrome, N. J.; the American Smelting & Refining Co., Omaha, Neb., and the Baltimore Copper Smelting & Rolling Co., Baltimore, Md., which includes all of the producers of these elements in this country. These companies will furnish workable quantities of selenium and tellurium for research purposes at cost price.

E. W. Rouse, of the Baltimore Copper Smelting & Rolling Co., Baltimore, Md., will ship at any time reasonable quantities of selenium gratis to investigators upon the recommendation of the committee on the uses of selenium and tellurium of the National Research Council. Arthur E. Hall, of the Omaha plant of the American Smelting & Refining Co., will forward reasonable quantities of tellurium gratis under the same conditions.

In times past various prizes have been offered in Europe for work on the utilization of such elements as bromine and boron. These elements at one time had a very restricted use. Selenium and tellurium, though practically useless at present, will unquestionably find their place as a useful necessity to man, but a large amount of research work is, of course, necessary.

Madison, Wis.

The French Iron and Steel Industry

The iron-ore resources of France before the war were estimated at 3,300,000,000 metric tons (metric ton = 2,204.6 lb.), or 300,000,000 tons less than those of Germany and 2,000,000,000 tons greater than England's. New basins have been discovered since 1910, and the French deposits, exclusive of those of Lorraine, are now estimated to be about 4,000,000,000 tons.

Aside from the new basins discovered, the relative resources of Germany and France (due to the recovery of the Lorraine basins) are at the present time: Germany about 1,270,000,000 tons and France 5,630,000,000. The exploitable iron-ore deposits of French North Africa (Algeria and Tunis) are estimated at from 100,000,000 to 150,000,000 tons.

The basins in the Departments of Meurthe-et-Moselle, Lorraine, Normandy, Anjou, Brittany and Pyrenees comprise the principal iron-ore deposits of France with an estimated tonnage of: Meurthe-et-Moselle, 3,000,000,000 tons; Normandy, Anjou, and Brittany, 200,000,000 tons; Pyrenees, 100,000,000 tons; Lorraine, 2,330,000,000 tons.

The production of iron ore in Germany, excluding Luxemburg but including Alsace-Lorraine, during 1913 was 28,608,000 metric tons, and in France, 21,918,000 tons. The estimates of possible production are: For Germany about 7,000,000 tons; and for France 43,000,000 tons and over, due to the recovery of Lorraine.

The principal iron- and steel-producing regions of France are:

The east, producing in 1912, 69 per cent of the pig iron, 55 per cent of the steel, and 43 per cent of the finished products.

The north, 17 per cent of the pig iron, 23 per cent of the steel, and 32 per cent of the finished products.

The center, 4 per cent of the pig iron, 12 per cent of the steel, and 14 per cent of the finished products.

The southwest, 5 per cent of the pig iron, 4 per cent of the steel, and 4 per cent of the finished products.

The west, 2 per cent of the pig iron, 3 per cent of the steel, and 4 per cent of the finished products.

The southeast, 3 per cent of the pig iron, 3 per cent of the steel, and 3 per cent of the finished products.

Alsace-Lorraine produced, in the first six months of 1919, 446 per cent of the iron, 32.1 per cent of the steel, and 28.4 per cent of the finished products manufactured in all France.

The Saybolt Viscosity of Oil Blends

A System of Charts for Determining Oil Blends of Components of Known Viscosity — Logarithmic Rule and Correction Factors to Be Applied in Calculations—Tables of Viscosities of Blends Containing 25, 50 and 75 Per Cent of Heavier Oil

By WINSLOW H. HERSCHEL

AS IS well known, the viscosity of a blend of two oils is less than the arithmetical mean of the viscosities of the component oils, but "there appears to be no simple law connecting the viscosity of a mixture with that of its constituents."[1] A convenient diagram for determining the viscosity of blends has been given by Espy[2] for viscosities between 300 and 55 seconds, Saybolt, but no equation is given by which the diagram may be extended beyond the range of his experiments.

This investigation has shown that the formula of Arrhenius, as given by Dunstan and Thole,[3] is of considerable help when used with suitable corrections. This formula shows that the viscosity of a blend is the weighted geometrical mean between the viscosities of the component oils, and may be written

$$\log \mu = v_1 \log \mu_1 + v_2 \log \mu_2 \qquad (1)$$

where v_1 and v_2 are the percentage volume concentrations, and μ_1 and μ_2 are the viscosities of the component oils, expressed in the absolute unit of viscosity, the poise.

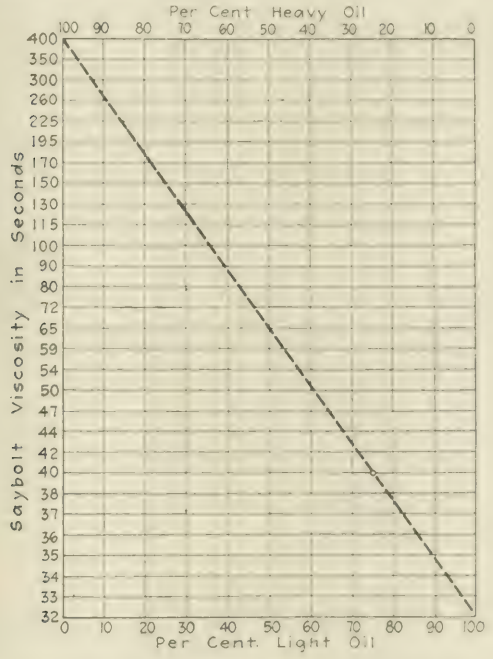

FIG. 1. CALCULATED VARIATION IN VISCOSITY OF A BLEND WITH THE VISCOSITY AND PER CENT OF OILS

Example: A blend of 40 viscosity, as shown by the point on the dotted line, may be made from 25 per cent of oil of 400 viscosity and 75 per cent of oil of 32 viscosity, both oils and blend being at the same temperature.

When the Saybolt Universal viscosimeter is used, the viscosity in poises may be calculated by the equation

$$\mu = \gamma (0.00220t - 1.80/t) \qquad (2)$$

where t is the time of flow, or Saybolt viscosity, in seconds, and γ is the density at the temperature of test, in grams per cubic centimeters.[4]

Since there is no definite relation between the viscosity and the density of oils (except when they are all from the same crude), and since it is generally assumed in the petroleum industry that two oils have the same viscosity if they show the same time of flow when tested in a viscosimeter, the effect of changes of density may be disregarded in approximate calculations.

Table I was calculated from equations (1) and (2) disregarding γ. It shows the Saybolt viscosities of blends containing 25, 50 and 75 per cent of either of the component oils. Each line of the table shows values of Saybolt viscosity for blends with a given viscosity of the lighter oil, the headings of the columns showing the viscosity of the heavier oil. Each rectangle formed by the intersection of a line and a column contains three values which are viscosities of blends of the two oils in question. Beginning at the top of a rectangle, these values are for blends containing 25, 50 and 75 per cent respectively of the heavier oil.

Blending Chart

On account of the large number of variables it is difficult to present Table I graphically. Fig. 1 is perhaps the most satisfactory form of diagram for a blending chart. Its form was due to Espy, but it was plotted from data of Table I.

According to Espy the data from a series of tests of two component oils mixed in all proportions are sufficient to enable a chart to be prepared which will be applicable to oils of all crudes. Higgins, however, made mixtures of Mexican with Scotch shale and Borneo oils, and found that the addition of 10 per cent of these latter oils caused the viscosity of the Mexican oil to be decreased 79 and 74 per cent in the two instances.

Tests at the Bureau of Standards

The first series of tests was made with two oils of approximately the same viscosities as those used by Espy and gave a fairly good check on his results. In order to get a large difference of viscosity between the two component oils, blends were made with gasoline and kerosene in Series 2. Equation (2) is not valid for viscosities less than 32 seconds, and for tests with gasoline it was necessary to use the Ubbelohde viscosimeter,[5] although the times of flow, as given in Table II,

Viscosities of heavier oil, for lighter oils *over* 160 vis. ← → Viscosities of heavier oil, for lighter oils *less than* 160 vis.

NOTE.—The three values in each rectangle are viscosities of blends of the three percentage compositions given above.

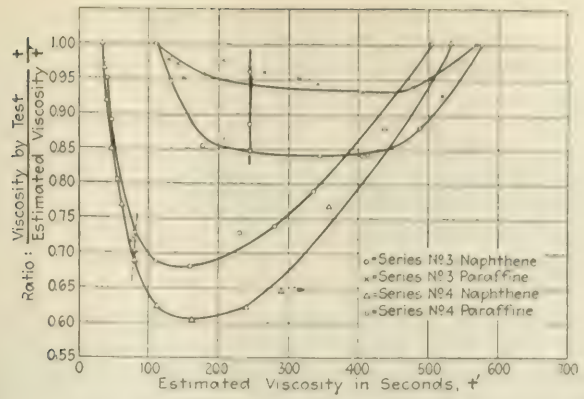
have been computed for the Saybolt viscosimeter. If μ is the viscosity of a blend as calculated from equation (2) and μ' is the viscosity, in poises, as estimated from the viscosities of the two components, then $\frac{\mu}{\mu'}$ is a correction factor by which the viscosities, estimated by equation (1), must be multiplied to obtain the values as given by test. $\frac{t}{t'}$ is a corresponding correction factor for Saybolt viscosities. It will be noted from Table II that there is considerable difference between the correction factors for viscosities in poises and in Saybolt seconds for a given test at low viscosities, but that the difference becomes negligible at high viscosities. Table II also shows that the logarithmic rule does not indicate as low a viscosity of blend as found by test, and that the error is very great when there is a large difference in viscosity between the component oils.

Tests of Series 3 and 4 were made to determine the effect upon the correction factors of varying the crudes. In Series 3 two heavy oils, N and P, one of naphthene and the other of paraffine crude, were selected of approximately the same viscosity at the temperature of test, and blended with two lighter oils, M and Q of the same crudes. It was found that the maximum correction factor was obtained for a blend of N and Q and the minimum factor for P and M, and it is noteworthy that these are both blends of unlike crudes. Results of tests on these oils mixed in various proportions are given in Table III, and it is seen that the correction factors are lower when the heavy oil is of naphthene than of paraffine base.

Results Obtained When Using Kerosenes as Diluents

In order to see whether this rule was still valid when kerosenes of the two crudes were used as diluents, the tests of Series 4 were run with the results shown in Table IV. The letters showing the source of the oils have the same significance as in Table III, but the viscosities of the oils are different.

It is seen that the naphthene base oil, in Table IV, is



Ratio: Viscosity by Test / Estimated Viscosity
Estimated Viscosity in Seconds, t'
o-Series No 3 Naphthene
×-Series No 3 Paraffine
Δ-Series No 4 Naphthene
u-Series No 4 Paraffine

FIG. 2. THE RELATION BETWEEN THE VISCOSITY AS DETERMINED BY TEST AND AS ESTIMATED BY THE LOGARITHMIC RULE

"cut" (thinned out) to a greater extent than the paraffine base oil, but the difference is not so great as in Table III.

In both tables the blends containing component oils of the same crudes show values of the correction factors which are intermediate between the extreme values for blends of unlike crudes.

Diagrams Used for Estimating the Correction Factors

Fig. 2 shows the results of tests of Series 3 and 4. It will be noted that the time ratio, or correction factor, is not a minimum for the 50 per cent blends, which are indicated by vertical dotted lines. While this form of diagram is convenient for interpolation in a given series of tests, it is not convenient for interpolation between one series and another.

In order to reduce the number of variables, it was decided to concentrate attention upon 50 per cent blends. If the correction factor for this blend is known, the factors for other proportions may be estimated by sketching curves similar in shape to those of Fig. 2.

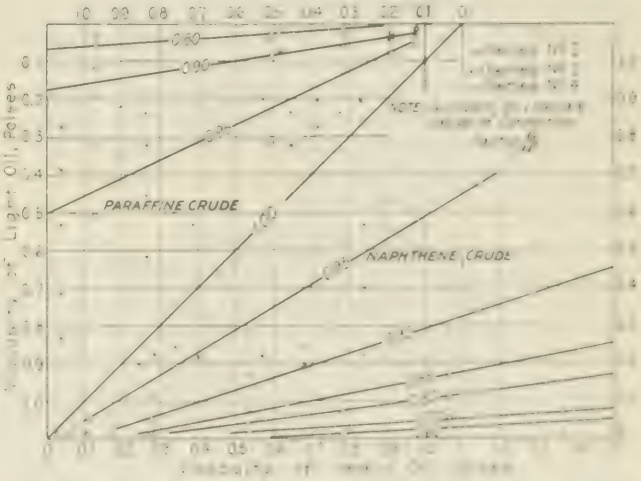

FIG. 3. DIAGRAM FOR ESTIMATING THE CORRECTION FACTOR FOR VISCOSITIES CALCULATED BY THE LOGARITHMIC RULE

The use of the correction factor $\frac{\mu}{\mu'}$ eliminates density and makes results more concordant than when $\frac{t}{t'}$ is used.

A blend of any proportion may be considered as a 50 per cent blend of two other blends, as for example, a 20 per cent blend is a blend of two others, one con-

taining 10 and the other 30 per cent of the component in question.

By estimating the viscosity of the 20 per cent blend from the experimentally determined viscosities of the 10 and 30 per cent blends, a new correction factor may be determined. Fig. 3 was plotted from correction factors obtained in this way.

The figure is divided into two sections by the diagonal line marked 1.00, the upper portion being for the blends P + M and the lower for N + Q. In plotting the diagram each point was marked with the corresponding value of $\frac{\mu}{\mu'}$ (not shown) and the lines drawn to conform as well as possible with these values, as in making a contour map.

Excluding steam-engine cylinder oils, and oils that are of too low a viscosity to be used in actual blending operations, the range is from about 1.5 to 0.12 poise. In the extreme case, therefore, the correction factor from Fig. 3 would be 0.75 for naphthene and 0.80 for paraffine crudes, corresponding to errors in viscosity of 33 and 25 per cent respectively. The errors in Saybolt viscosity would be somewhat less.

The estimation of the viscosity of blends containing cylinder stock presents an additional difficulty on account of the error in measurement of viscosities due to the change of volume of the oil after leaving the outlet tube. There is thus a possibility of serious disagreement between viscosities estimated by the use of Fig. 3 and experimental results, when cylinder stock is used at temperatures approaching the boiling point of water, unless precautions are taken to avoid the error above mentioned.

Conclusion

A table of viscosities of blends has been calculated from the logarithmic rule which is inaccurate but is the best available. The larger the difference in viscosity of the component oils the greater will be the error in the rule. For equal differences of viscosity the error increases as the viscosity of the lighter component decreases.

Diagrams are given for finding the correction factor for 50 per cent blends, and for then estimating the correction factors for blends of other proportions.

U. S. Bureau of Standards.

A Bankrupt Philosophy

"My emphatic conclusion is that Socialism as a philosophy of possible human application is bankrupt. The whole of the various sorts of Socialism are based on one primary conception, and that is that the productivity of the human being can be maintained under the impulse of altruism, and that the selection of the particular human for this most productive performance can be made by some superimposed bureaucracy. Their weakness is the disregard of the normal day-to-day primary impulse of the human animal—that is, self-interest for himself or for his family and home, with a certain addition of altruism varying with his racial instinct and his degree of intelligence. They fail to take into account, also, that there is but one sufficiently selective agent for human abilities in that infinite specialization of mind and body necessary to maintain the output of the intricate machinery of production, and that is the primary school of conception."—Herbert Hoover, in *The Nation's Business*.

Peat Fiber and the Textile Industry

Swedish efforts to introduce peat fiber as a substitute article in the textile industry have come to naught for the moment. It is the consensus that the prices for extracting the fiber from peat moss must be economical before it will ever come into general use. Two factories, one in Denmark and the other at Partille, near Goteborg, both established during the war for the purpose of utilizing peat fiber, have had to close their doors in recognition of this fact.

One of the leading exponents of the uses of peat fiber was Prof. Gustaf Sellergren, of Stockholm. It was upon his application that the Swedish Government recently caused an investigation regarding the possibilities of utilizing the vast deposits of peat moss in Sweden in the textile industry of the country. The experts appointed to make the investigation have completed their labors, and, among other things, found:

(1) Good textiles of peat fiber and "shoddy" can be manufactured and samples were demonstrated, but

(2) The Swedish peat mosses can produce only 100 kilos of fibers and moss per day, which is not sufficient for commercial purposes.

(3) The methods so far used in obtaining the fibers are too expensive.

The experts concluded by proposing that no further action be taken in the matter until the peat mosses could be examined carefully with regard to the amount of fiber contained, which work is within the province of the Swedish Committee on Geological Examinations and the government's peat engineers serving in the Swedish Department of Agriculture.

Prof. Sellergren states, however, that his methods have not been tried, and that his patent rights for Sweden already have been sold. He claims to have some very fine samples of textiles made of peat fiber, and says that while his interest in this fiber has been cooled by the findings some day he may return to the subject. He claims that Swedish peat mosses contain on an average 15 to 20 per cent peat fibers and that they should be utilized in connection with the fabrication of peat litter.

Treatise on Pyrometric Practice

The Bureau of Standards has completed the manuscript of a comprehensive treatise on modern pyrometry under the title "Pyrometric Practice." The object of this treatise is to provide investigators, manufacturers and others who may be concerned with the measurement of high temperatures with complete information as to the present state of the art of pyrometry, the instruments and methods used, the precautions that must be observed to obtain correct results, and to illustrate some of the industrial applications of pyrometry. The scope of the paper is indicated from the following subheads: Temperature scale; high temperature thermometry; thermal electrical pyrometry; optical pyrometry; radiation pyrometry; resistance thermometry; recording pyrometry; high temperature control; melting point methods at high temperatures; standardization of pyrometers and industrial applications of pyrometry. This paper will be ready in six to nine months. The completed volume will consist of 300 pages and will contain a large number of illustrations. The number for free distribution will probably be small, but provision will be made by which it can be obtained at cost from the Superintendent of Documents.

Elastic Properties of Bronze Castings

A Series of Tests Showing That a Definite Proportional Limit Can Easily Be Found for Bronzes, and the Suggestion Made That This Test Should Replace the More Usual but Illogical "Yield Point" Determinations

BY GEORGE F. COMSTOCK
Metallurgist, Titanium Bronze Co.

IN COMMERCIAL practice it has become customary to determine the so-called "elastic limit" or yield point of non-ferrous alloys as the tensile stress producing a deformation of 0.01 in. on a gage length of 2 in. The chief advantages of this method are its ease of application and the facility with which concordant results can be obtained by different operators on the same material. It is generally conceded that the "drop-of-the-beam" method, which is used for rolled soft steel, cannot be applied to non-ferrous alloys; and if the smallest appreciable deformation is taken as the criterion of the yield point, difficulties are at once encountered in agreeing as to what constitutes an appreciable deformation. Thus the figure of 0.01 in. has been recommended and apparently agreed upon as representing the smallest practical deformation that can readily be measured with dividers in determining the so-called "elastic limit" of non-ferrous alloys.

It is a question, however, whether this determination really gives us any information of value. It is intended, of course, to show the stiffness of the material, and what stress it would safely bear in service without bending or stretching. Yet it is obvious that the yield-point stress as so defined is appreciably more than enough to start deformation in the metal, and there is no way of telling from this determination at what stress the deformation really began. For trustworthy information on this point it is necessary to determine the true elastic limit or proportional limit of the material, and the accustomed use of the yield point in this connection is not correct, as there is no direct relation between it and the proportional limit. As has been stated by J. A. Capp in his paper on "The Elastic Limit of Manganese and Other Bronzes," before the American Society of Mechanical Engineers in 1910, "The real object of testing is to determine the characteristics of a material so that one may decide what shall be safe stresses in any structure, taking into account the elastic properties of the material, etc. Usually such safe loads are a certain proportion of the elastic limit. If, however, the elastic limit is determined by erroneous tests to be double its true value, any calculation based on such data is utterly unsafe."

This same idea applied to steel was enlarged upon by A. N. Mitinsky in "Some Suggestions Regarding the Determination of the Properties of Steel," published in the *Bulletin* of the American Institute of Mining Engineers for August, 1915, p. 1,697, but the author probably carried it a little too far in claiming that fatigue resistance is determined solely by the proportional limit, and that the wear of rails is also dependent on it.

The best definitions of elastic limit, proportional limit and yield point are undoubtedly those given by the American Society for Testing Materials in its "Standard Methods of Testing," and it is assumed that they are sufficiently well known not to require repetition here. Reference should also be made to the discussion on elastic limit, etc., in the *Proceedings* of this Society, vol. 16, part 2, p. 404. Some writers, as Howard, Upton in "Materials of Construction," and Thurston in "Materials of Engineering," do not make any distinction between elastic limit and proportional limit. Others, such as Lynch, Olshausen and Moore, hold that there is a difference between these limits, the true elastic or "set" limit being higher. Moore feels that the difference may be due to initial stresses in the material, or the limits of precision of the apparatus, or other similar causes. He has also stated that the determination of the proportional limit depends in no small degree on the sensitiveness of the apparatus used; while Morse, on the other hand, claims that in determining the proportional limit an extensometer of low precision gives the same result as one of high, though the latter is necessary for the elastic limit.

Elastic Behavior of Non-Ferrous Metals

The idea that ductile non-ferrous metals, especially in the cast condition, do not have any definite elastic limit, proportional limit or yield point is quite prevalent in the literature. For instance, in Upton's "Materials of Construction" the statement occurs (p. 23) that "there is no very definite elastic limit" in castings of ductile materials tested parallel to their surfaces or lengths, but in this case "the loading line is slightly curved from the beginning." Also he says (p. 29) that "the ductile materials other than steels usually have either non-isotropic crystals or very large initial internal stresses. These conditions prevent the fairly simultaneous yielding of all parts of the structure. The beginnings of yielding of the individual crystals are distributed over a considerable range of the loading. So in brasses and bronzes, for instance, we miss the decided yield-point action of the steels." Thurston, in his "Materials of Engineering" (part 3, p. 245), even goes so far as to say that non-ferrous metals "have usually, as purchased, no true elastic limit, but yield to small stresses without recovery of form, and their permanent set equals their maximum distortion." C. A. M. Smith, in a paper before the Institute of Metals on "The Elastic Breakdown of Non-Ferrous Metals" (*Journal*, vol. 2, p. 151), reported variable results obtained with his very delicate "sphingometer" for the measurement of minute strains, but in the discussion Parker stated that while lack of homogeneity in cast non-ferrous alloys probably accounted for 75 per cent of the cases of inequality of stress distribution in testing, yet in spite of this the elastic limit was not greatly affected.

This belief that cast non-ferrous metals do not have any real elastic limit, or any definite limit of proportionality of strain to stress, is one reason for the adop-

tion of the arbitrary criterion of 0.5 per cent elongation as marking the so-called "elastic limit" or yield point to be used in ordinary commercial work. Another reason is the assumption that the determination of the real elastic limit or proportional limit is too difficult for this class of work, and involves the use of expensive and delicate apparatus and considerable time. Corse and Skillman evidently took this attitude in their paper on "Manganese Bronze Tests" before the Eighth International Congress of Applied Chemistry (vol. 3, p. 25), for although urging that the usual yield-point determinations on this material are useless, they do not suggest taking the proportional limit instead, but would rely entirely on the tensile strength and elongation. Capp, in his paper on Manganese Bronze quoted above, considered not only that a delicate extensometer was necessary for proper determinations of the proportional limit, but that the gage lengths of the test bars should be 8 in. Nearly all authorities agree that this test must be made with spherical-seated holders for the specimen, and with an accurate extensometer averaging the deformations on two or three sides of the bar, and even then it is claimed by some that non-homogeneity of the specimen and inequality of stress distribution may obscure the real effects of inelastic action in the results. Therefore it has come about that proportional limit determinations have been considered as too refined and expensive for the ordinary commercial tests of bronzes, and the easier but almost worthless yield-point method has been retained instead.

Elastic Tests on Bronzes

During the past few years quite a large number of tests have been made in this laboratory on several types of cast bronze alloys with a view of determining fairly closely their true elastic properties. The measurements of elastic limit and proportional limit have been made in different ways, and although the instruments used have been of the simplest type, the results have been so consistent as to be of interest in showing what can be done along this line with almost crude equipment. It has also been brought out how truly deceptive the commercial yield-point determination is, and the results are probably worth emphasizing merely to prevent undue reliance being placed upon that determination. Another point which it is believed has been demonstrated is that ductile non-ferrous alloys, even when cast, do have a definite limit of proportionality of strain to stress.

A variety of alloys was used in this work, but the most complete results were obtained from manganese bronze, aluminum bronze with 10 per cent aluminum and 1 or 4 per cent iron, and the common gun-metal or zinc bronze of about 88-10-2 composition, including both the G and Pc2 specifications of the Navy Department, the latter allowing a much wider range of tin and an appreciable lead content. The manganese-bronze test specimens were cast in the form of keel-blocks, the aluminum-bronze as plain round bars, and the zinc-bronze specimens were cast in nearly the final size and shape, and fed through a lengthwise fin. The test specimens were all machined to approximately $\frac{1}{2}$-in. diameter between shoulders, and the gage length was in all cases 2 in. A few tests were made with specimens having plain ends, and pulled in ordinary wedge grips, but the results obtained in this way were too irregular, and it was soon recognized that the specimens must be pulled in grips having spherical seats through which the tension would be applied without any bending. The grips used here were fitted to receive a specimen with threaded ends, but similar grips intended to engage with extra shoulders on the ends of the specimens would probably be equally satisfactory.

The testing was all done with an Olsen Universal three-screw machine of 100,000-lb. capacity, but the lighter poise reducing the capacity to 10,000-lb. was used for nearly all the work below the yield point in order to increase the delicacy of the load measurements. The autographic mechanism supplied with this machine for drawing load-deformation diagrams was rejected as not being sufficiently sensitive with gage lengths of only 2 in., and a Berry strain gage was used in its place. Several methods of applying this instrument were tried. At first it was clamped to the test specimen and used as an extensometer, as shown in Fig. 1, the deformations in this case being read on only one side of the specimen. Although this method is not favored by most writers on this subject, it has been defended by J. J. Shuman in discussing Lynch's paper on "Elastic Limit" (*Proc.* A. S. T. M., vol. 15, part 2, p. 417).

Results With Strain Gage in One Position

In the first series of tests of cast specimens (not heat treated) the loads were applied in increments of 200 lb., the strain gage reading for the load was taken, and the load was removed to get the permanent set. This procedure was repeated for each load until the permanent set became about 0.0003 in.; after that the loads were not removed between increments, and the deformation only under load was measured each time. When this became greater than 0.01 in. the strain gage was removed, and the test specimen was broken in the usual way. The strain gage was graduated to 0.0002 in., and

the readings taken were estimated to a tenth of this value, or 0.00002 in. The stress-set and stress-deformation curves were plotted on cross-section paper to a scale such that 1 in. vertically represented 5,000 lb. per sq.in., and 1 in. horizontally represented 0.002-in. extension on the gage length of 2 in., or 0.1 per cent deformation.

Tests on the heat-treated aluminum-bronze test specimens were made in the same way, except that a heavier poise was used on the machine, the increments were 500 lb. instead of 200, and the stress scale used in plotting was such that 1 in. represented 10,000 lb. per sq.in.

The results were obtained from the curves in the following way: The yield point was the stress at which the deformation curve crossed the line representing 0.01-in. extension, and the proportional limit was the stress at which this curve ceased to coincide with a straight line drawn through most of the points at the lower part of the curve. The elastic limit was the stress at which the set curve departed from an approximately vertical direction, sets of 0.00002 in. being generally neglected unless the next set recorded was considerably greater. The tensile strength, elongation and reduction of area were determined in the usual way after removing the strain gage and breaking the specimen. The moduli of elasticity were also read from the curves, but were not considered reliable, as will be explained below.

The results obtained in this way are listed in Table I, and some of the curves noted by a star and typical of each alloy are also illustrated in Plate I. The figures given represent pounds per square inch, or, in the case of the elongation and reduction of area, per cent.

Results Using Strain Gage in Three Positions

In all these tests it was found that the elastic limit was lower than the proportional limit, except in a few cases where both appeared about equal. According to most authorities, however, the elastic limit, if not equal to the proportional limit, should be slightly higher. Consequently the possibility of serious error in the above results was feared, and it was felt that this might have arisen from the manner of using the strain gage, that is, along one line only of the test specimen. Furthermore, many of the deformation curves were not as regular as might be desired, although the proportional limit was quite distinctly marked in all of them. To check the accuracy of the proportional limits tabulated above, it was therefore decided to test other specimens of these alloys, with the strain gage applied successively to each of three gage lines, equal distances apart around the surface of the specimen, for every load used. The test specimens were prepared, and held in the testing machine, in the same way as was previously described, but the loads used were 400, 800, 1,200, and every 200 lb. above that until the proportional limit had surely been passed. The gage was placed in each of three pairs of punch marks by hand three or four times at each load, and the average reading for each pair of marks was recorded. Considerable care was necessary in holding and reading the gage in this way, for the reading could be varied appreciably by changing the manner of applying the gage. It was not thought practical to drill holes into the specimens for the reception of the gage points, for with a small specimen such as was used in this work, premature failure would be almost certain to occur through the drilled holes. The loads were not released in these tests to determine the permanent sets, because it was not thought possible to apply the gage to the specimens accurately enough by hand to measure the very minute differences in length that these sets represent; also because attempts to get these measurements would have consumed very much more time. Therefore elastic limits are not reported for this series, and these tests were not carried far enough with the strain gage to get the yield points.

Three stress-deformation curves were obtained by this method for each specimen, and they were plotted to the same scale as has been described above. An average curve was also plotted by using the average deformation at each load, and it was always more regular in form than the three curves of actual measurements.

TABLE I. RESULTS USING STRAIN GAGE IN ONE POSITION

*Illustrated in Plate I.

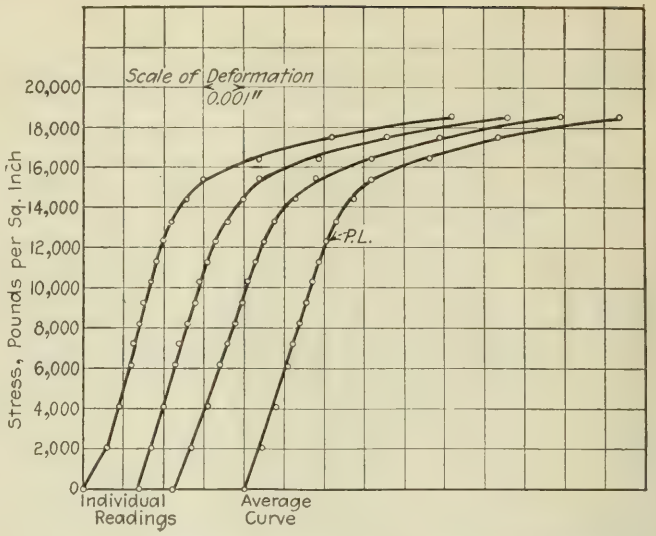

FIG. 2. STRESS-DEFORMATION CURVES FOR ZINC-BRONZE Pc2, TEST 32. GAGE LENGTH, 2 IN.

The true proportional limit and modulus of elasticity were determined from it, the latter being the stress divided by the extension per inch, for any point on a straight line drawn through most of the points of the lower part of the average stress-deformation curve. The results are presented in Table II in the same form as before, and typical average curves noted by a star for each alloy are also illustrated in Plate I.

TABLE II RESULTS WITH STRAIN GAGE IN THREE LOCATIONS

Test No.	Proportional Limit	Modulus of Elasticity	Tensile Strength	Elongation, Per Cent	Reduction of Area, Per Cent
		Zinc-Bronze, Alloy G			
29	8,000	11,000,000	33,800	21 5	22 9

36*	20,500	16,000,000	71,000	9 0	10.4

* Average curves for these samples listed in Plate I.

In explanation of Table II it should be noted that both of the Alloy G specimens (tests 29 and 30) turned out to be unsound, so that their lower proportional limits

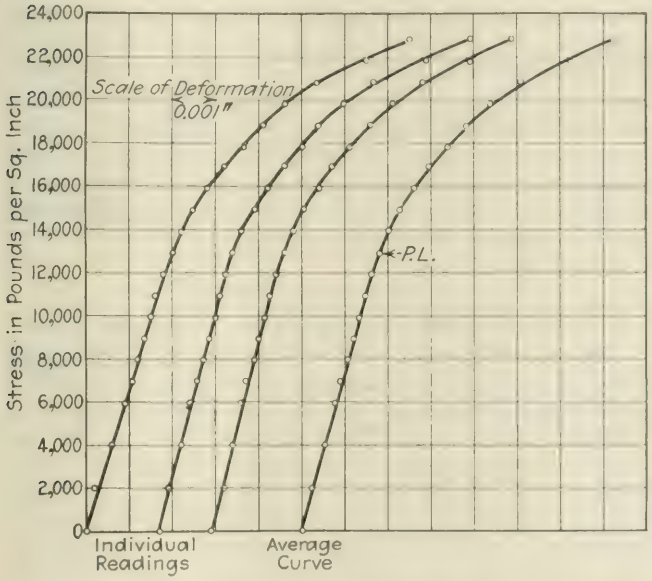

FIG. 3. STRESS-DEFORMATION CURVES FOR ALUMINUM-BRONZE, WITH 1 PER CENT Fe, TEST 35. GAGE LENGTH, 2 IN.

as compared with the previous tests (Nos. 1 to 4) might be expected. Also the specimen of aluminum-bronze with 4 per cent iron had been cast in sand 1¼ in. in diameter, and had been allowed to cool too slowly, so that it was somewhat annealed. This lowered the strength and ductility but raised the proportional limit. With these explanations the proportional limits check in a satisfactory manner those determined by using the strain-gage as an extensometer. It may be noted, moreover, from all the curves, such as those for zinc-bronze, alloy Pc2 (illustrated in Fig. 2) and for the aluminum-bronze containing 1 per cent iron (Fig. 3), that in the case of every specimen a proportional limit determined from one of the individual strain-gage curves would be just the same as the result found from the average

FIG. 4. HOME-MADE EXTENSOMETER, WITH AMES DIAL FROM BERRY STRAIN GAGE, SHOWING METHOD OF USE IN THE THIRD SERIES OF TESTS

curve for that specimen. This shows that no serious errors occurred in the proportional limit determinations of the first series of tests because of the use of the gage along only one line on the surface of each specimen. This is seen not to hold true for the modulus of elasticity, however, as the slopes of the individual curves vary considerably (Figs. 2 and 3), which shows that no true idea of this modulus can be obtained from the first series of tests. The curves from the heat-treated aluminum-bronzes were so regular and uniform that it was not thought necessary to check them in the second series.

Results Using Special Extensometer

Some of the individual curves of the second series were very irregular in their lower portions, on account of the great difficulty of placing the strain gage on exactly the same marks on the specimen accurately for each measurement. To eliminate this trouble, and to check the elastic limit and modulus of elasticity figures already obtained, an extensometer was constructed that could be kept attached to the specimen till after the yield point was passed, and that would measure the average deformation along two sides of the specimen. The same dial was used in the extensometer as in the strain gage, and the frame of the extensometer was constructed somewhat on the pattern of the instrument described before the Society for Testing Materials in 1915 by S. H. Graf (*Proc.* A. S. T. M., vol. 15, part 2, p. 376). In our instrument shown in Fig. 4, however, the motion transmitted from the test specimen to the dial is magnified five times by levers, as is done in the strain gage

itself, so that a unit on the dial represents the same deformation of the specimen, whether it is on the strain gage or on the extensometer.

Tests were made with this extensometer in exactly the same way as was described above for the first series of tests, the only difference being that the deformations measured in this third series were average deformations from two sides of the specimen, instead of being from only one side. The curves obtained in this way were more regular, and determinations were made of the elastic limit and modulus of elasticity as well as the proportional limit, yield point, etc. The results are listed in Table III and some typical curves noted by a star are also shown in Plate I.

* These curves shown in Plate I.

Discussion of Results

Allowing for individual variations in the test specimens, these results are in fairly good agreement with those given before. The proportional limits are nearly all lower than in the other series, but most of these specimens were of somewhat softer material as shown by the tensile strengths. The elastic limits check those in the first series, and the moduli of elasticity agree with those in the second series, except in the case of the manganese-bronze, where there is a considerable difference probably due to a different quality of metal.

It seems quite evident from this work that the elastic limits of these cast bronzes are nearly always found lower than the proportional limits, and never higher. The writer does not attempt to explain or defend this statement on theoretical grounds, but the curves certainly seem to demonstrate its truth.

Another point brought out clearly by the curves and tables is that there is no uniform relation between the proportional limit and the yield point or tensile strength in these alloys. Comparing tests 37 and 38, for instance, the latter showed a decidedly higher yield point (and modulus of elasticity) due to separation of the copper-tin eutectoid in greater amount, but its real proportional limit was as low as in the other specimen. Also the zinc-bronzes have distinctly lower yield points and much lower tensile strengths than aluminum-bronze with 1 per cent iron, yet the proportional limits of these two alloys are practically the same. When heat treated, however, the aluminum-bronzes are far superior to any of the other non-ferrous alloys in elastic properties, and the method of treatment leaves them free from internal stresses so that their proportional limits are very distinct and easily recognized.

No claim can be made for exceptional accuracy in these tests, but it has been demonstrated that a definite proportional limit can be found for non-ferrous castings without any great refinements of testing such as would be impractical in commercial work. When it is not desired to determine the elastic limit or modulus of elasticity, the proportional limit can be found with little trouble by means of a Berry strain gage attached to the test specimen and used as an extensometer. It is necessary, however, to pull the specimen with spherical-seated holders.

Of course any of the good extensometers on the market can be used with at least equally good results, and any of the methods for proportional limit determinations that have been described before the Society for Testing Materials may be followed.

It is suggested that for acceptance tests of non-ferrous castings the rough determination of the yield point as the stress giving a deformation of 0.5 per cent should be discarded as of no real significance, and that the importance of tensile strength measurements for this class of material should also not be emphasized, but that proportional limit determinations should be made and used for acceptance or rejection of bronzes that are intended to resist stresses in service. Ductility as expressed by a good percentage of elongation is probably a necessary quality to guard against brittleness; but as a measure of stiffness and useful strength without distortion, the proportional limit and not the yield point should be employed. That this can be done as readily in non-ferrous work as with steel is the chief conclusion to be drawn from the tests that have been described.

Acknowledgment should be made of the assistance of Austin B. Wilson in making many of these tests; and the author is also indebted to the Titanium Bronze Co. for the test specimens on which the work was done and the extensometer used, and to the Titanium Alloy Manufacturing Co. for the use of the testing machine and other laboratory facilities.

Niagara Falls, N. Y.

Exports of Crude Rubber From Brazil and Peru

The total shipments of crude rubber from the ports of Para, Manaos, and Itacoatiara, Brazil, and Iquitos, Peru, during the month of January, 1920, amounted to 6,273,039 lb., as compared with 6,624,915 lb. in the corresponding month of last year. Shipments from these ports during February totaled 8,162,264 lb. in 1920, as against 9,242,309 lb. in 1919; and the March shipments were 6,916,352 lb. in 1920 and 9,512,787 lb. in 1919. The price of this commodity still continues low and the effect of the low price is seen in the refusal of merchants to place large orders for forward delivery.

New Uses for Stainless Steel

Stainless steel is being employed very largely in the manufacture of pump rods, valve spindles, valves and other parts which are exposed to contact with water, steam and other corrosives. The scientific-instrument trade is using it for drawing instruments and other precision tools and for surgical instruments. It is being manufactured into stair rods, saucepans and pans of varying shapes, fenders for the hearth, and even into pokers and garden implements; and butchers' rails, spikes, skewers, saws and other butcher-shop requirements are being made from it. Sport is also taking an interest in stainless steel and is promoting a demand for golf-club heads, spurs, etc.

Scientific Control of the Filter Station—III

A Discussion on Washing and Drying Filter Cakes—Blowing With Air or Steam to Displace Filtrate, Wash Liquor and Water — Operations Fundamentally Dependent on Cake Formation*

By ARTHUR WRIGHT, M.E.

UNDOUBTEDLY present-day filtration is marked more by the advance in labor-saving devices than by any other feature of modern type filters. More economies, however, have been made in the better washing of the cakes in the new type filters, for whereas residual soluble in the cakes was formerly counted in whole per cents, today it is in fractions of 1 per cent. Materials that needed exacting washes were not handled in filter presses, the wash water in which almost always left some parts of the cake incompletely washed, yet these materials are today handled most efficiently in the modern filters.

The reason for the better results obtained is found in displacement washing. This is the term used to define that wash in which the liquid entrained in the voids of the cakes is pushed ahead of the wash water without the latter mixing with the liquid. In practice it is the simple filtering of the wash water through cakes the surfaces of which are equi-resistant.

All credit is assuredly due George Moore, who first realized the value of an equi-resistant cake and made it the foundation of his patents, both process and apparatus. His discovery was the factor which saved the cyanide process of gold extraction from being a pretty laboratory experiment and made it the forerunner of the efficient systems now employed.

Uniform Resistance to Flow Desired

The explanation for the practical production of an equi-resistant surface is had by reference to Fig. 5. Take any points *A*, *B* and *C* on the cakes, which may have been uniformly built up or may be tapering cakes the bottom of which is thicker than the top. The resistance to the flow is the same at all of them while filtration is taking place. The proof of this is found in assuming that at *A* the resistance is less than at any other point; then, according to the law of the flow of liquids, which seek the path of least resistance, a greater flow must pass through at the point *A*. Since, however, muddy liquor enters the filter and clarified liquid issues from it, the greater flow at *A* creates a greater deposit of the solids of suspension and this obviously increases the resistance to the flow until it is equal to the point *B* or the point *C*. It must, therefore, be acknowledged that during filtration, and at the close of the filtering cycle, the cakes present an equi-resistant surface to the flow of the filtrate.

The advantage of an equi-resistant cake surface must be apparent in obtaining a uniform wash of the cake. When the wash water cannot penetrate any part of the cake faster than any other, it forces the liquid entrained in the voids of the cake through as undiluted filtrate. This, of course, is the end desired, but it must not be thought that all the soluble can be recovered without some dilution even with the best types of filters and with the most expert manipulation. The bulk of the soluble can and should be so regained, but due to capillary attraction and dead end pores of porous material some soluble is retained and lags behind that forced out from the interstices of the cake. This liquid is recoverable by diffusion with the wash water and regained as a sweet water or weak liquor.

These facts are brought out in the graph known as the Washing Curve shown in Fig. 6. This is a plot obtained from periodic readings of the amount of wash filtrate flowing and its density. The abscissæ are the gallons flow and the ordinates the density.

Wash Liquor Displacement of Filtrate

Assuming the density of the filtrate to have been 32 deg. Bé., the curve of the theoretical ideal displacement wash is seen to be a broken straight line and is interpreted as meaning that all of the soluble is recovered at the high density and when all is forced out the density falls to that of the wash water. This is, as explained above, impossible in practical operation and has its value only when serving to note the efficiency of the practical operation.

The leaf-displacement curve is typical of good operation in leaf type or continuous filters. It will be noted that there is a gradual fall from the maximum density before the sharp break occurs. The explanation for this is that the viscosity of high density liquids is greater than that of the wash water or low density liquids. When washing commences the cakes present an equi-resistant surface, but as the wash water penetrates the cake some parts of the cake are made slightly less resistant so that the water flows through somewhat faster at such points. The turn of the curve before reaching zero is the result of the capillary attraction above referred to.

Washing Efficiencies of Plate and Frame Presses

The curve depicting the wash in plate and frame presses is representative of that obtained from alternate plate system of washing. Here the wash water finds channels and quickly weakens the strong effluent, causing a fall in the specific gravity. For the same reason, an effluent of a gravity equal to the wash water is obtained only by using excessive quantities of wash water. The reason for this is quite evident when we comprehend the conditions obtaining. In a plate and frame or chamber filter press initial filtration is analogous to that of leaf type filters and varies from this latter practice only when the cake on adjacent filter cloths in each frame meet. From that point on, the pump, feeding the press, does work not of cake building but cake compressing. This of itself is not a serious drawback, but it is practically impossible to compress all of the cake evenly or completely. It must

*For Parts I and II, see CHEM. & MET. ENG., vol. 22, Nos. 22 and 23, June 2 and 9, 1920, pp. 1,015 and 1,077.

also be remembered that the initial path of the wash water from the alternate plates is in a direction counter to that of the filtrate which produced the cake. This counter-current of the wash water is vital. The resistance of the cake to a counter-current wash is seldom equi-resistant, for it is the exception when the frames are completely and evenly packed. Consequently, it is obvious that paths of less resistance are open to the flow of the wash water and universal practice demonstrates the inadequacy of alternate plate methods of washing filter press cakes.

Plate and frame presses of a sluicing type such as the Merrill Press and automatic discharge type such as the Atkins-Schriver employ the displacement system of washing and have registered marked successes in their washing efficiency. To work ordinary plate and frame presses on this system is to invite nice control if discharging troubles are not to be encountered.

Original Formation of Cakes Must Be Preserved

From the foregoing it is seen that the formation of the cakes must be preserved if true displacement wash is to be obtained in leaf filters. Most materials in plant operation vary from time to time in their filtering characteristics so that in leaf filters it is generally found that there is too much unfiltered material to allow the wash water to be turned on directly at the close of the filtering cycle. To do so would surely mean a dilution of the strong liquor lying in the filter and to increase unduly weak liquor production. Practice, therefore, requires drawing the excess from the filter before the introduction of the water. This method allows materials to be washed at the end of their economical filtering cycle and is equally applicable whether the cakes are thick or thin. This feature of leaf filters is an important one and is in contrast to the operation in plate and frame filters, where the cake must be built up until it fills the frames and filtration ceases when the frames are filled. With raw materials varying in percentage soluble so that the material of suspension varies in amount and character, filtering until the frames are full often entails filtering long after the economical limit is reached.

Skill Required in Operation

Unfortunately this method of washing is successful in direct proportion to the ability of the operator. It is in his power to transfer the unfiltered material and fill with wash water so that the cakes remain in a condition practically as equi-resistant as when finishing filtration or he can defeat the desired ends by failing to maintain the equi-resistant surface. It is positively important that he be instructed not only what valves to operate but should be impressed with what he is trying to effect so that he can visualize the conditions inside of the machine. If he fails to maintain a positive pressure, usually by means of compressed air, some cake will slough off the cloths and surely create a path of less resistance for the passage of the wash water. The same is true if he drains or blows back the excess liquor at too great velocity. Again, if he uses too high air pressure, when holding the cakes on the leaves, he is almost positive to dry the upper part of the cakes in advance of the lower part and will either crack the cake or cool it so that in either case it is conducive to the formation of unequal resistances to the flow of the wash water. Obviously this makes for selective washing. Then, too, if he takes too long time in substituting wash water for the excess unfiltered liquor the conditions are the same as though he used too high air pressure. Experimentation will dictate the best pressure to use and the operator when once realizing what he must safeguard against has no trouble in effecting admirable results.

The Direct Washing Method

When handling materials that run uniformly the filters can be designed so that the space between adjacent cakes at the end of the economical filtering cycle will be minimized. With Sweetland type leaf filters, in which excess space in the filter is small, it is then practical to switch on the wash water simultaneously with the closing of the liquor valve. The excess unfiltered liquor is forced through the cake ahead of the water and the dilution of the strong liquor by the water is negligible. The same is true of Merrill type and Atkins-Shriver type plate and frame presses.

The direct washing method, the name given this system of admitting the wash water without withdrawing the excess unfiltered material, is not only advantageous on the score of simplicity of operation and saving of time but allows the greatest approximation to the true displacement wash. The reason is clear, for there is no possibility of any cake sloughing off the filter cloth, no cracks to be developed by air drying and the equi-resistant condition of the cake is automatically preserved so long as there is a positive pressure maintained in the filter during the transfer from feeding liquor to admitting wash water.

It is interesting to note that the quantity of sweet water or weak liquor produced should approach as an ideal that amount which equals the volume of the voids in the cake. It has been explained wherein capillary and absorptive action require something in excess of

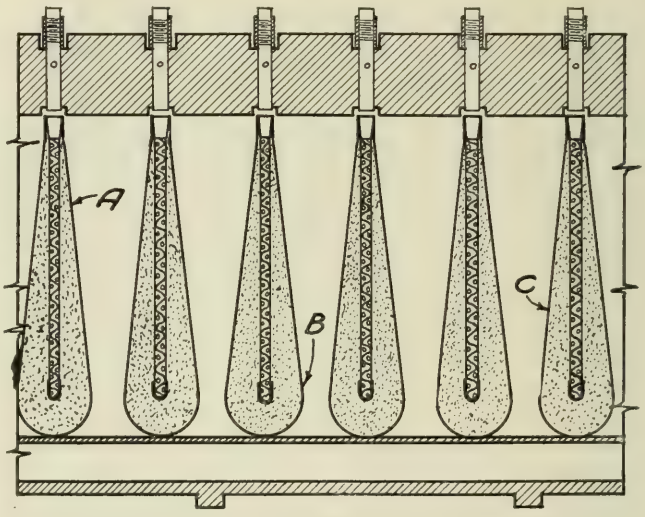

FIG. 5. EQUI-RESISTANT CAKE FORMATION

this in practice, but the actual amount required is oftentimes reduced when the impoverishment of the strong liquor is done by degrees.

By this means the gravity prevailing when fresh water is turned on is much reduced from the original gravity. In practice weak liquor washes are used for this purpose so that all water entering the process leaves it as a strong liquor. The same scheme is worked with marked success in continuous counter-

current decantation installations save that a semi-dewatered solid instead of an equi-resistant surface is subjected to the weak liquor washes.

Spray Wash for Continuous Filter Cake

All of this discussion relative to an equi-resistant surface is equally pertinent to washing the cake in continuous vacuum filters. Here the wash water is applied as an atomized spray, but in theory at least the water sprayed on the cake should, in its passage through the washing arc, envelop the cake and be equivalent to submergence. Excessive amounts of water are unnecessary and will run off the cake. This is, of course, objectionable, but the operator should not go to the other extreme of applying too little water, for then air-drying commences and the wash water will often be short-circuited. It is for this reason that with cakes difficult to wash out the soluble it is advisable to augment the spray wash with a repuddling of the discharged cake with water or weak liquor and filtering and washing on a second machine. This makes for fool-proof and efficient washing especially if the spray wash on the first machine is the effluent from the second machine. Then the strong liquor in the cake of the first machine is recovered at a high gravity.

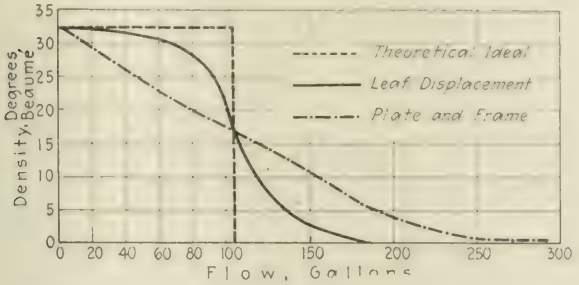

FIG. 6. CHANGE OF DENSITY OF WASH LIQUOR

Advantages of Open Gravity Filters

When handling extremely free-filtering solids such as calcium sulphate from phosphoric, citric, etc., acid manufacture, it is surprising how well the soluble can be extracted in open gravity filters. These filters can usually be home-made machines with false bottoms covered with cocoa matting, burlap, etc., or with the old cinder bed bottom. The one essential point is that the liquor and the wash water must drain by gravity so that the cake is built up uniformly. The cake formed is granular and allows considerable flow per unit surface, but the percolation of the wash water is slow enough so that shortly after the heavy liquid in the voids of the cake is displaced the remaining soluble has had time to diffuse through the wash water. This accounts for the admirable wash obtained in this class of filters, which obviously is confined only to those materials of an extremely free-filtering character. New means of discharge of the cake from this type filters will be described in the article under "Discharging" appearing in a later issue, wherein the manual labor hitherto entailed with this type of machine is obviated.

Drying the Cakes

Drying the cakes is a part of the operation of industrial filters often definitely required but too often thought unnecessary. Dryness of discharge is obviously advantageous when a further drying operation is required. When recovering the soluble from the cakes, oftentimes the cake is a waste product and the percentage of moisture in the cake is not a vital consideration save as a safeguard against high losses of soluble in the discharge cake. If the washing operation has been efficient, drying the cake is superfluous, but if defective washing has taken place, then decreasing the moisture content decreases the soluble in the cake.

Drying the cake is fundamentally dependent on the formation of the cake. If a compact cake is produced, the voids in the cake are minimized; if a fluffy cake is formed, the percentage of voids is large. In either case the work of drying the solids is the removal of the liquid in the voids. Obviously those cakes having low percentage voids require less duty on the drying operation than those with high void content.

Advantages of Recessed Plate Filter Presses

Plate and frame or recessed plate filter presses stand in a class by themselves as filters delivering dry cakes. The reason for this is explained in that the cakes are more compact than those obtained from any other type filter. The initial filtration in filter presses is identical with that in leaf or continuous filters except when filtration has progressed so that the cakes on adjacent filter cloths meet; then the filtration in filter presses varies from the filtration in modern type filters in that the pump begins to do work of cake compression rather than continuing that of cake forming. It is this cake-compressing action that helps so materially in the production of cakes of low voidage.

With the above in mind it is therefore evident that there is a definite width of frame for each material in order that efficient operation of the filters and the discharge of the driest cakes be obtained. Too wide a frame requires too long a cake-building period and allows too great a resistance to the flow to be set up before the work of cake compression commences. It is thus seen that for any particular material there is a balance between the maximum caking capacity of a press and the dryness of the cake, consistent with efficient operation. In the writer's experience these data are best determined by experimentation on a single leaf filter when the filtering characteristics of the material are determined without giving thought to dryness of discharge.

The principle of cake compression for dryness of discharge is unfortunately not applicable to leaf type filters. Here the cakes must not be allowed to form so as to touch each other or otherwise all the advantages of displacement washing and self-discharge are jeopardized. Also overcharging in pressure leaf filters is insidious in its evil effect of warping the filter leaves. The difficulty from tearing the cloths on distorted leaves and from straightening the drainage members is apparent, but in a well-designed and well-operated machine the filter leaves are spaced so that the cakes do not meet. When the leaves are bent out of shape it is practically an impossibility to straighten them completely, at least while in the filter, so that the original spacing is changed and some of the leaves are on closer centers. This, of course, is a condition ripe for continuing this difficulty and becomes a constant source of trouble. It is not generally understood just what produces the distortion of filter leaves. It is not that the leaves bend away from the cakes which have joined together but that by their having joined together the pressure between them is lowered while the exposed

sides of the leaves are subject to the full pressure. This gives an excess force which, acting over the entire surface, exerts enough pressure to cause the leaves to bend in toward the joined cakes.

Moisture Displacement by Compressed Air

Drying the cakes in leaf type filters, therefore, must be obtained by displacing the entrained liquid in the voids of the cakes by some gas (compressed air, steam, etc.). This part of the filtering cycle is undoubtedly the weakest in the operation of leaf filters. To start with, the cakes, as built up, are high in percentage voids, a mere examination of the cake showing the exterior of the cake to be far wetter than that against the filter cloth, and the bulk of the liquid extracted from the cakes must pass through an ever-increasing resistance until penetrating the filter cloth. This, of course, entails a high duty on the drying agent.

When drying with compressed air, which is in reality filtering compressed air through the cakes, the effect is to supplant the liquid in the voids of the cake with air. This obviously is less support for the particles of the cake, so that there is a rearrangement of the particles—generally spoken of as the "shrinking of the cake." This shrinking results in cracks developing which immediately form paths of less resistance for the passage of the compressed air. At this stage the drying effect is negligible in comparison with the work of compressing the air and best practice is to halt the drying operation at this point.

Prevention of Cracking of Cake

Best drying operation in leaf type and continuous vacuum filters is obtained, therefore, by proceeding in that manner which decreases the early formation of cracks. With granular and similar materials this is so practical that the difference of percentage moisture in cakes of such materials as discharged from modern filters and moisture in cakes as discharged from filter presses is not large. When handling fine, flocculent materials it is more difficult to prevent early cracking. The procedure in such cases is to build up as dense a cake as possible before admitting the compressed air and to remove as much moisture in the cake at as low a pressure as possible. The means of forming the dense cake can best be determined by experimentation, but it is often found that if the initial filtration be carried on at a low pressure and allowed to rise to a point considerably less than that used during the washing operation, good results are obtained. In vacuum continuous filters, especially those of the drum type, flapping and cake-compacting mechanisms can effect this result mechanically. In any design of vacuum continuous filters where cake cracking cannot be avoided there is a big saving on the duty of the vacuum pump if the automatic valve be constructed so as to shut off the suction at the time of crack formation.

Leaf type filters constructed so that the outlet of the leaves is at the top of the leaf are not as satisfactory as those that drain from the bottom. The reason for this is quite apparent, for bottom-discharge leaves drain out all the liquid, whereas the top discharge pockets the liquid and on discharge that liquid is forced back through the cloth and mixes with the discharge cake. This is the advantage of bottom-drainage filter leaves and is the only reason for drier cakes being obtained from their use.

It is a proved fact that many materials may be discharged from leaf or continuous type filters higher in percentage moisture than cakes of the same materials discharged from filter presses and yet in subsequent driers will be found to work better. This is due to the cake formation admitting a better heat conductivity and escape of the steam vapor. True, if the cake from the filter presses be broken up, then the advantage lies with the filter press cakes.

Firmness of Cake

It is somewhat academic but nevertheless important to understand clearly the theory of cake formation, which bears such a relation to drying efficiency. When a filter is first started up or when a section of a continuous filter first dips into the liquor the rate of flow is the greatest. The flow may quite as readily be conceived as the summation of the delivery from every square inch of surface. On each unit area, cake is being deposited and its compactness is in direct proportion to the velocity of the liquid being filtered. When the velocity is high the stream lines are said to be strong, and weak when the velocity is low. Therefore, if the velocity be maintained at a high rate for a long period, the stream lines are strong and the cake firm. This then gives the reasoning on which better drying effect is obtained when starting with low pressure for the handling of difficult filtering materials because this low initial pressure does not build as resistant a cake and admits of a greater flow throughout the cycle thereby. Obviously the cake produced by strong stream lines must be a dense cake if we consider the cake as being built up by arresting the particle of suspension carried by the stream lines (its momentum being in direct proportion to the velocity of the stream line). The greater the momentum the greater the impact upon the cake and the denser the cake produced.

(Part IV, dealing with Discharging, will be published in a subsequent issue.)

Hongkong's Imports of Chemicals

The trade in chemicals at Hongkong in 1919 showed little life and very little increase over that of 1918. The total value of the trade is given by Hongkong official statistics at $2,572,755, compared with a value of $2,265,582 in 1918.

The chief items in the trade were saltpeter, which reached a value of $459,659 and came almost entirely from India; camphor, valued at $288,935, supplied mainly by north and middle China and Japan; soda ash, $228,342, almost entirely from Great Britain; caustic soda, $194,696, of which two-thirds came from the United States and most of the rest from Great Britain; and the usual run of miscellaneous drugs and chemicals, none of which reached $100,000 in value. There was a marked decrease in the imports of acids, most of which came from Japan, and also smaller imports of bleaching powder (in quantity, though the value stayed about the same for the two years), calcium carbide, phosphorus and glycerine. There were increased imports of alum, borax, quinine, chlorate of potash and sulphur.

In a general way Hongkong importers found it difficult to secure supplies from the United States and most of them returned to their old British connections as rapidly as conditions permitted. Present exchange conditions militate against local industries, and this is reflected in the lessened demand for chemicals.

Extraction of Tannin From Indian Myrabolans

THE following note on myrabolans (myrobalans), the fruit of *Terminalia chebula*, prepared by the tannin expert of the Government of India, appeared in a recent issue of the *Indian Trade Journal:*

The myrabolan fruit—or, as it is often incorrectly called, the "nut"—is usually collected when still green. After collection it should be promptly dried in the sun. The best grades of myrabolans, viz., the Bhimlis and Jubbulpores, are collected in this way. Bombay nuts are riper when collected and are apt to be somewhat soft, waxy and spongy. They have a smoother skin with larger wrinkles than Jubbulpores and Bhimlis, and are, as a rule, less liked by the trade, but have been reported to be actually richer in tannin than the harder, shriveled, first-grade nuts.

In Europe myrabolans are the best-known Indian tanstuff, and find a very wide application in mixture tannages. In India myrabolans are largely used in mixture tannage, and perhaps still more largely as a "bleaching" agent at the end of the tanning process. This is especially in the case in the tannage of the "crust" leathers of Bombay and Madras with avaram or turwad (*Cassia auriculata*), when the tannage is completed by a bleaching process in a brew of myrabolans. For this purpose, myrabolan extract would not be suitable, but in mixture tannages extract could be utilized to replace the myrabolans at present used. For tannery use myrabolans should be crushed before extracting the liquors.

Myrabolans have also long been known as a dyestuff. They are, for instance, used in Bombay for the production of yellowish-buff shades on cotton. Myrabolans also find some application in the manufacture of inks, which are produced by the addition of iron salts, suitable gum, and some "soluble blue" dye. In Europe, myrabolans are used in the dyehouse for the mordanting of cotton as a preparation for the application of basic dyes, the weighting of black silk, etc.

Nuts for Export

Spongy nuts, which do not keep so well as shriveled nuts, might be used for the preparation of a "No. 1 crushed" myrabolan product. For this, the nuts would be crushed with a wooden mallet as soon as collected, and the comparatively valueless stones removed. The remaining flesh should be dried in the sun, when, if the nuts were in sound condition when crushed, the product should show approximately some 50 per cent tannin.

From the economic standpoint it would really be better to crush all myrabolans intended for export abroad and to dry the flesh in the sun. Removing the useless stones would effect considerable economy in freight while enhancing the proportion of the valuable tannin constituent in the product exported. There is, however, a prejudice on the part of the European public against crushed myrabolans, because, when exported in this finely divided form, the addition of adulterants is easy to effect and difficult to detect. Crushed myrabolans, therefore, could only be exported where an absolute and unimpeachable guaranty of genuine purity could be given and the quality always maintained over a long period. On the other hand, whole nuts cannot well be adulterated, and if of good grade will always secure their prices, even when sold by an unknown vendor. They should contain 30 to 40 per cent tannin.

The percentage of tannin in a solid extract should approach very nearly to 60 per cent. The gain in concentration over the best whole nuts is therefore very considerable, although much less so in the case of the pure crushed product without stones.

Advantage of Extract Over Raw Product

Although a solid myrabolan extract is not much richer in tannin than the crushed stoneless product, it consists, in the main, of soluble matters plus water, whereas the crushed raw product contains vegetable fibrous matter which adheres to fabrics in the dyehouse and also to the leather in the tanyard. In the latter case, however, it is not a very serious objection, and in the case of bleaching with myrabolans the product crushed is in its most effective form for the purpose; but crushed myrabolans could not be used to strengthen tan liquors materially, as the tannin principle is dissolved from it relatively slowly, whereas solid myrabolan extract is readily soluble.

Myrabolans will produce a very good paste extract of, say, 40 or 50 deg. Tw. The solid extract, also, has long been a commercial product. It is, however, inclined in moist, warm weather to become soft and sticky, at least on the surface of the block; this owing to the affinity for water of certain of the non-tannin constituents in the extract. Their presence makes it doubtful whether it would be advisable to prepare the myrabolan extract in crystal form except for use in cold countries. In hot, moist climates such crystals would be likely to re-cohere into a solid mass, though it is possible that this difficulty may be overcome in the course of time. Apart from this hygroscopic tendency, myrabolans produce a good, clear extract which is fairly free from insolubles and has good keeping qualities. The extract is readily soluble in water, but dilute solutions very soon deposit "bloom" or ellagic acid. It is the loss of some of this "bloom" during concentration to solid extract that renders the extract less suitable than the raw material for the so-called "bleaching" process.

Process of Manufacture of Extract

The process of manufacturing the extract may be divided into three sections—(*a*) crushing, (*b*) leaching or extracting, and (*c*) conversion of relatively weak leach or extractor liquors into extract.

(*a*) Suitable machines are available for crushing the myrabolans in such a way that the useless stones drop out. The tannin principle of myrabolans is so inclosed in the cells that it is not very easy completely to extract the raw material, and it is for this reason that figures of yield nearly approaching the theoretical possible are so seldom attained.

(*b*) For the best extracting or leaching, series of connected leaches or extractor pits or vats are required. Water passes first over all but exhausted raw material and then into a series of pits over less and less exhausted material, until in the final pit, before it is drawn off, it passes over absolutely fresh material, this pit being regarded at the moment as the head of the series. The pit, however, over which pure water had been passed to extract the last traces, is now emptied and filled up with fresh raw material, and in its turn becomes the head of the series, the pits always being worked in a circular rotation.

(*c*) The liquors from leaches are allowed to settle in a suitable pit, or in some instances are subjected to

filtration at this stage. The clear liquors are then drawn by vacuum into a multiple-effect vacuum evaporating system in which they are rapidly concentrated (in a few hours at most) to a liquor of say, 50 per cent solids strength. The liquors are then pumped, or drawn by vacuum, into a finishing evaporator which is usually of the Calandria type. Here the thick liquors are further concentrated during several hours to a paste, which will just flow from the pan while still hot. The extract in this form is collected in paper-lined boxes, and in the course of a night will set to solid. When properly prepared, myrabolan extract should be readily soluble in water, giving an amber to amber-brown solution. The solid extract should have a clear, bright, vitreous fracture.

If myrabolan liquors are concentrated to solid in the air, much decomposition of the tannin ensues; the extract is black in color and contains objectionable tarry decomposition products.

The Alsatian Petroleum Industry

During the present time of fuel shortage the petroleum wells at Pechelbronn, in Alsace, have taken on a new importance. These wells are of considerable value. They were first discovered in 1735; a few years later a small refining plant was constructed, and the wells have been worked for about 180 years. They are among the oldest petroleum wells in the world. In 1888 underground digging was replaced by the modern boring method; but during the war the older method had to be resumed, and shafts were driven to a depth of 275 yd. These petroleum deposits are now the only ones in the world worked by shafts. This method of exploitation is made difficult by the fact that the beds of sand under the earth become impregnated with inflammable gases and a slight accident will cause a serious explosion. Two thousand workmen are now engaged at Pechelbronn in various kinds of work, including the location of new deposits of oil, the extraction of the crude oil, distilling, refining, etc. Pechelbronn produces 50,000 tons of petroleum products per year.

Modern Equipment—New Deposit Recently Tapped

All branches of this flourishing plant are equipped with the best modern machinery. The drilling machines, of which there are forty-four, are run by electricity or steam and are distributed over a surface of 110,000 acres. A network of electric wires, over 42 km. (26 miles) in length, furnish power to about 500 oil pumps. Three shafts, with 4,000 m. (13,000 ft.) of subterranean galleries, produce more than 25,000 tons of crude petroleum per year.

Recently a drill driven to a depth of 435 m. (1,427 ft.) in a region hitherto untouched located a new deposit, and the well is now spouting petroleum at the rate of fifty tons a day. New refineries are to be installed capable of distilling 73,000 tons of crude petroleum per year. The distillation is to be by the "continuous" process, with perfect vacuum.

These Pechelbronn petroleum deposits are of great value to France at the present time, not only because of the fuel which they yield but because of the information which French capitalists are able to obtain from them as to the best method of handling petroleum deposits in which they are interested or have concessions in foreign countries.

Legal Notes

By Wellington Gustin

Rodman Patent for Method of Making Case-Hardening Material Held Valid

The Rodman patent, No. 1,076,453, for a method of making case-hardening material, has been held valid and infringed by the United States Circuit Court of Appeals, Seventh Circuit, reversing the District Court. Suit for infringement of the patent was instituted by the Rodman Chemical Co. against the Deeds Commercial Laboratories. The invention relates to improved methods of manufacturing carbonizing material for dry packing. The product of this process is small masses or pebbles of carbonizing material, made out of what was theretofore largely waste dust. The advantage over other carbonizing products was its reduced costs, due to the utilization of a waste product, its greater thermal conductivity, easier handling over powdered or dusty carbonizing materials, and especially its retention of identity under heat.

The claims of the Rodman patent in the suit were Nos. 1, 7, 10, 17, 22, and 25. Claim 1 follows:

"1. The method of adapting finely divided material for use as carbonizing material, which consists in mixing the material with a binding agent and forming small masses which will maintain their identities when heated."

Claim 22 differs only in describing the binding agent as "tacky" and claim 25 by adding after the words "binding agent" the phrase "such as molasses." In claim 7, the method of forming "small rounded pebbles," instead of "small masses," is stated as "tumbling to form." Claim 17 reads:

"17. The method of preparing carbonizing material which consists in fashioning finely divided material into substantially smooth-surfaced pebbles and in then applying heat thereto."

The Deeds Commercial Laboratories defended the suit, claiming that the process had been used for more than two years prior to application for patent. Another defense was that the process had been anticipated and was invalid for lack of invention, while still another was non-infringement. The District Court for Indiana found for the defendant on these grounds, but this judgment was reversed on appeal.

Claims of Prior Use Denied by Court

On the question of prior use it was found that the Rodman Chemical Co. manufactured successively and contemporaneously several kinds of carbonizing materials; and that the product from the method of the patent under suit was the final and most successful one. This differed in substance, in form and in quality from the others, each marking an advancing step in the manufacture of a valuable commercial product, yet each produced by a definitely distinct method. Proof showed that the method of the patent was not used prior to 1912, and the patent was granted Oct. 21, 1913.

On the question of infringement the court said there was infringement, except as to claim 7, if the claims are to be broadly interpreted. The defendant used charred carbonaceous materials in powdered form and

a solution of molasses and water; they are mixed in a mixing machine, small balls or pills being produced The proper sized ones are first air-dried, and are then dried in a revolving drum with heat applied. The purpose of this final heating was alleged to dry out the excess moisture, yet the effect thereof in this revolving drum is to reduce the size of the pills and to compact and harden them. Whether this be technically a "tumbling" operation or not, it is the equivalent thereof; the sole purpose of tumbling is to compact or harden the pill; and whether this be accomplished in one operation, during their formation as pills, or in two, is immaterial. In his claims Rodman is not confined to the use of such carbonaceous material as requires coking, and the court said that defendant's use of coked or charred powder as against Rodman's preferential method of using coking coal dust does not therefore avoid infringement.

While some carbonaceous materials, like charred leather, require no special preparation, others, like charcoal, coke, or coal, require, for commercial use at any practicable temperature, the addition of a chemical energizer, such as lime, in order to activate the carbon. But the patent is not limited to the use of a carbonaceous material requiring the addition of an energizer. The carbonizing material in each of the claims covers as well carbonaceous materials, such as charred leather or corncobs used by defendant, having in themselves sufficient energy to activate the carbon.

Court Discusses Case Hardening

On the question of anticipation and want of invention in the patent, the court discussed case hardening as presented to it. Case hardening is a species of carbonizing. If it be desired to harden the metal throughout, carbon is dissolved into the molten metal. If, however, only the surface is to be hardened, so-called case hardening, the finished product is packed in dry carbonizing material; the box is sealed and placed in a red hot furnace for several hours; the carbon gases produced are absorbed only by the surface of the metal. When the required depth of carbonization is secured, the article is dropped, red hot, into cold water; this makes the carbon skin or "case" perfectly hard. The interior of the article, not having been carbonized, remains soft and tough. The desirable and sought-after product for case hardening was one that would be susceptible of repeated use; the small pill, maintaining its identity when heated, answered this need. The uniform distribution of carbon and energizer, resulting from their use in powdered form, and the maintenance of this relation by the permanent binding together of the particles, as well as the freedom from dust, were additional advantages of this pill or pellet formation. Moreover, a waste material, the coal or coke dust, heretofore discarded was utilized.

A new product was thus created; a product of commercial value for definite uses, said the court. Earlier patents, Dodds, British, No. 571; Aube, British, No. 738; Demenge, No. 564,053; Logan, German, No. 181,-531; all of which mention incidentally case hardening, and Meyer, No. 524,904, while referring to the use of carbonizing briquets made of powdered materials or of balls of carbonizing paste, give no hint that these products will not be completely absorbed in a single carbonizing process, or that they will maintain their identity under heat; nothing whatever is said in any of them as to the method of manufacture. The court said they were different products than those made under the process of the patent in suit.

While each step in the process of making these pellets may be old as applied to other articles, the conception of this novel product and of the combination of acts necessary to produce it is novel, said the court. In the light of the present knowledge, it may have been a simple matter for defendant's expert, from a reading of the earlier patents, to create a product identical with that of the process in suit and by the same means; this, however, is no demonstration that the product or method would have been obvious to one skilled in the art but ignorant of the patent in suit.

Rodman's essential contribution to the art through the patent was the step by which the identity of the small pellets was maintained, and their continued use in actual practice for about 500 hours made possible. And the court held that defendant made a substantially identical product by a substantially identical method, resulting in infringement.

Uses of Duralumin in Aëronautics

The National Advisory Committee for Aëronautics at its recent semi-annual meeting acted favorably upon the recommendation of the committee on materials for aircraft and adopted the following resolution:

> *Resolved*, That the executive committee be instructed to communicate with various manufacturing companies, inviting their attention to the importance of duralumin products, especially tubing, for airplane wings, and endeavoring to secure their co-operation in the development of duralumin products for airplanes.

It is considered to be a highly essential matter that duralumin and similar wrought aluminum alloys, as well as aluminum castings alloys, be made available for military use. It is also anticipated by the metallurgical experts that a large commercial future can be expected for these materials, not only in commercial exploitation of airplanes, but also in automotive construction and in other industrial work where strong, light alloys are much needed.

Metal parts of Zeppelins were made of aluminum alloys and the later ships were all of duralumin. In the United States a considerable amount of duralumin metal has been produced in simple shapes, while in England, France and Germany the production has been carried to almost all conceivable wrought shapes. For example, Fokker all-metal planes have duralumin wing coverings replacing fabric, duralumin frame-work in various welded and formed shapes and duralumin tubing for the supporting members.

German Potash Situation

In the *Times Trade Supplement* (London) of April 10, 1920, the following interesting article on the German potash situation was published:

"At a general meeting last month of one of the most important concerns in the German potash combine it was reported that the present position of the German potash industry is very unhealthy. Exports in 1919 were 3,000,000 metric hundredweight, as against a pre-war exportation of 12,000,000 to 16,000,000. The home supply was actually worse in 1919 than in the previous year, falling from 16,000,000 to 12,000,000, whereas before the war about 24,000,000 metric hundredweight was furnished. Of the 200 potash works in the combine 80 were shut down entirely last year. It is noted that the individual output of the workers fell from 149 tons in 1918 to 65 tons in 1919."

Vulcanized Fiber

By L. R. W. Allison

The increasing popularity and utility of vulcanized fiber for electrical, mechanical and other purposes lends particular interest to this material and its composition. Up to the present time but brief information has been published on the subject, indicating that a broadened knowledge will prove decidedly advantageous in various channels of operation.*

Vulcanized fiber has assumed an important status in the manufacture of parts, tubing, rods, bushings, washers and disks, etc., replacing die-stampings and other metal productions for numerous specialties. Its use is not only becoming standardized, but phases of manufacture are being improved to that degree to insure absolute certainty as to service and life.

The industry as a whole has grown to a noticeable extent during the past few years, and leading manufacturers, not content with immediate accomplishments, have been studying further possibilities.

How Vulcanized Fiber Is Made

Vulcanized fiber is manufactured from cotton rag stock, which, after being cut into small pieces, is boiled with soda, washed, bleached and beaten to a pulp; it is colored red or black, or left in its natural gray state, and then run off on paper machines, which convert it into a high-grade cellulose paper, both unsized and unadulterated. The paper subsequently is passed through a bath of zinc chloride in which its surface is gelatinized to such an extent that, on being "built up," the various layers become as one homogeneous sheet of any thickness desired.

These sheets are in turn treated to remove and neutralize the chemical reagents, after which they are dried and calendered, then cured or seasoned for a period varying up to one year, according to the thickness. The importance of natural aging or seasoning will be appreciated when it is understood that any attempt to force this process, for the purpose of cheapening the product, invariably results in an inferior material. In such event, the ultimate life of the fiber is lost or shortened and its dielectric strength impaired.

Properly prepared vulcanized fiber, because of its toughness, elasticity and durability, is superior to hard rubber and porcelain for electrical or mechanical purposes. In its finished form it does not shrink, warp, twist or expand unless exposed to moisture; and when used in moist places, gives satisfactory service if coated with shellac or other moisture-excluding compound.

Fiber Tubing and Fiber Rods

Fiber tube has become an important material in electrical insulation, due to its properties and the ease with which it may be made into any desired shape. This tubing is prepared in the manner explained above. The paper is gelatinized and run on steel mandrels of a size which determines the inside diameter, while the number of turns establishes the wall thickness, or the outside dimension. In the electrical industry, fiber tubes are being used very generally for flashlight cases, cable conductors on automobiles, vacuum-cleaner nozzles, and the like.

Fiber rods are made from sheet fiber. The sheet is cut into square bars and then run through a rod or dowel machine. Accurate diameters are obtained to 2 in., with 5 ft. as the standard length. This rod may be used for the same purposes as metal rod and for any special parts usually made from metal, such as bushings, screws, push buttons, and so on.

Fiber can be machined very easily and accurately, and into practically any shape. It can be embossed with equal facility and takes a very fine finish.

Standard Sizes Manufactured

Standard sheets of vulcanized fiber as produced by the Mitchell-Rand Manufacturing Co., New York, come in a size of 44 x 72 in. The thickness varies from 0.005 in., weighing approximately 0.8 lb. per sheet, to 1 in., which weighs about 160 lb. per sheet.

Fiber tubing is manufactured with an inside diameter varying from $\frac{1}{8}$ in. to 6 in., and with thickness of wall in $\frac{1}{32}$-in. variations, from $\frac{1}{16}$ in. to $\frac{3}{8}$ in. Up to 1 in., the inside diameter increases by $\frac{1}{16}$-in. measurements, and above this diameter by $\frac{1}{8}$-in. variations. The lengths vary from 2 to 3 ft.

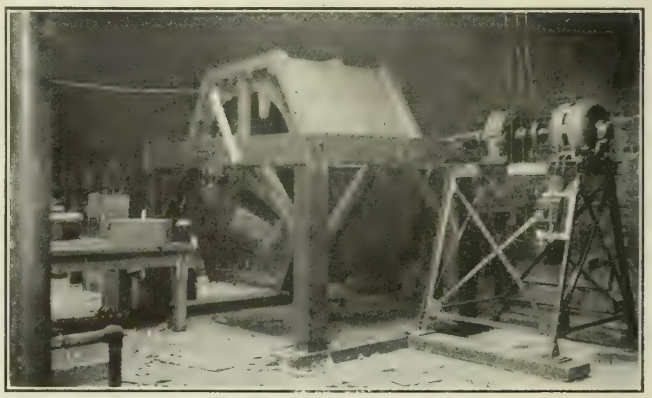
Newark, N. J.

*A concise statement of the manufacture and properties of vulcanized fiber, by Charles Almy, Jr., appeared in Metallurgcal & Chemical Engineering, vol. 13, p. 746 (Oct. 15, 1915).

Drum Tester

In a test for strength of shipping boxes, the object of which is a simulation of the rough knocks, bumps and jars of handling which a loaded box may encounter in railroad traffic, there has been designed a machine by which the railroad usage which a box may meet in a 2,000-mile haul can be duplicated in four or five minutes.

The first machine of this kind—known as the drum box-testing machine—was designed by the U. S. Government Forest Products Laboratory at Madison, Wis.



DRUM BOX-TESTING MACHINE

The machine installed at the Mellon Institute is an improvement over the original tester in that the inconvenience of overhead pulleys and shafting has been done away with by the substitution of a reduction gear for cutting down the motor speed to the drum speed of 2 r.p.m.

A valuable field of investigation and scientific study of the construction and materials of packages is opened up by the new machine, such as best methods of interior and exterior packing for fragile or irregular shaped objects; the determination of proper specifications for containers carrying various commodities, etc.

The Container Club of Chicago, an association composed of corrugated and solid fiber box manufacturers of the United States, offers free service in the designing of scientific packing methods for the various commodities capable of being shipped in fiber containers.

Recent Chemical & Metallurgical Patents

Toluene From Xylene.—To the fraction of solvent naphtha which is obtained between 135 and 145 deg. C. and which consists principally of metaxylene, is added 5 to 10 per cent of anhydrous aluminum chloride. The latter combines with a portion of the xylene to form the active catalyst, which is a reddish liquid not miscible with the hydrocarbons. Upon distilling this mixture under suitably regulated conditions, the toluene is removed as rapidly as formed. Plugging of the column and condensers due to volatilized aluminum chloride is avoided by distilling under a 14 in. vacuum. (1,334,033 and 1,337,317; ARTHUR E. HOULEHAN of Wilmington, Del., assignor to E. I. du Pont de Nemours & Co.; March 16, 1920 and April 20, 1920.)

Continuous Electrical Mechanical Filter.—For removing colloidal and other fine suspensions from liquids, ARCHIBALD F. MESTON, of New York, has devised a continuous filter in which the colloidal particles are agglomerated prior to filtration by electrostatic action. The revolving drum forms one electrode. The other electrode is hollow so that the liquid to be filtered may be fed in through it. Difference of potential is maintained by current from the secondary winding of a transformer. (1,334,160; assigned to Research Corporation; March 16, 1920.)

Metallic Sodium.—Many of the difficulties encountered in the Castner process for the production of metallic sodium by the electrolysis of fused NaOH are overcome in the process devised by ALBERT W. SMITH and WILLIAM R. VEAZEY, of Cleveland. The electrolysis of a mixture of 35.6 parts of sodium chloride and 64.4 parts of sodium carbonate yields metallic sodium equal in quality to the present commercial product. This mixture melts at 600 deg. C. (1,334,179; assigned to the Dow Chemical Co.; March 16, 1920.)

Sulphuric Acid Plant Construction. — It has been customary to support the lead curtain walls and tops of sulphuric acid towers and chambers by means of independent wood or steel structures, whether or not such towers or chambers contained interior masonry walls or packing. These methods have involved heavy and expensive framing especially in those cases where it was desirable to use towers or chambers of considerable height. ELDON L. LARISON, of Anaconda, Mont., proposes to construct towers or chambers of this type in such a way that the lead sheathing of sides and tops with the necessary light framing to which the supporting lead straps are attached shall be supported on the masonry walls. Construction details are given. (1,334,384; March 23, 1920.)

Adsorption of Vapors and Gases by Silica Gel.—Silica gel is an efficient adsorbent for many gases and vapors. During adsorption, the evidence seems to indicate that under certain conditions the gas is actually liquefied in the pores. This effect is obtained under conditions of temperature and pressure widely different from those under which ordinary liquefaction takes place. Thus 100 to 200 atmospheres pressure is required at 0 deg. C. to liquefy the SO_2 out of air containing 1 per cent SO_2. On the other hand, air containing 0.5 per cent SO_2 may be passed through 29 g. of silica gel at 0 deg. C. at the rate of 400 c.c. per minute for two or three hours before the exit gases will show more than a trace of SO_2.

The adsorbed SO_2 may be recovered by passing a slow stream of air through the gel at a higher temperature. By proper regulation of temperature, pressure and rate at which air is admitted during liberation of the adsorbed SO_2, any desired mixture up to practically 100 per cent SO_2 may be obtained. Several drawings of apparatus for the recovery of sulphur dioxide evolved during metallurgical operations are given in the patent specification.

For a brief review of the theory of the adsorption of vapors by silica gel, see CHEMICAL & METALLURGICAL ENGINEERING, vol. 22, p. 949, May 19, 1920. (1,335,348; WALTER A. PATRICK, BENJAMIN F. LOVELACE and ERNEST B. MILLER, of Baltimore, Md.; March 30, 1920.)

Use of Sludge Acid in the Manufacture of Hydrochloric Acid.—A mixture of equal parts of sludge acid and sodium chloride is diluted with 10 per cent of water and heated to not more than 284 deg. C. in a still composed of a lead-lined pan covered by an acid-proof tile arch. The addition of water causes the asphalt and tarry matter to be liberated and to rise to the surface of the solution, so that loss of sulphuric acid through reduction by the carbon in these materials is avoided. The hydrochloric acid gas given off during the heating is purified by passing through towers containing sodium chloride. For the purpose of absorbing the gas in water, the inventor, HENRY M. LASHER, of Kansas City, Kan., describes three types of apparatus: a closed tank into which the gas is passed through a perforated coil; a horizontal absorber in which the flow of gas and water is concurrent; a horizontal counter-current absorber. (1,335,743, 1,337,141, and 1,339,519; assigned to Kansas City Refining Co.; April 6, April 13, and May 11, 1920.)

Magnesium Chloride.—A process for the recovery of magnesium chloride from Michigan brines containing, in addition, calcium chloride and sodium chloride, was described by EDWIN O. BARSTOW in U. S. P. 1,209,245 issued Dec. 19, 1916. It was based upon the reaction:

$$CaCl_2 + MgSO_4 = CaSO_4 + MgCl_2$$

An improvement in this method has been devised by HERBERT H. DOW and EDWIN O. BARSTOW, of Midland, Mich. The calcium is removed from the brine by treatment with sodium sulphite obtained as a byproduct in the manufacture of phenol. Since such Na_2SO_3 contains some carbonate, two reactions occur:

$$CaCl_2 + Na_2SO_3 = CaSO_3 + 2NaCl$$
$$CaCl_2 + Na_2CO_3 = CaCO_3 + 2NaCl$$

After filtering off the insoluble $CaSO_3$ and $CaCO_3$, the solution contains $MgCl_2$ and NaCl. By evaporating to 34 deg Bé. the NaCl separates out. The mother liquor is further evaporated until it corresponds in composition to $MgCl_2\ 6H_2O$, when it is drawn off into drums and allowed to cool and solidify. (1,336,425; assigned to Dow Chemical Co.; April 13, 1920.)

Nitric Acid From Ammonia.—In order to avoid the use of large and expensive absorption towers for the conversion of nitric oxide into nitric acid, ELIHU

THOMSON, of Lynn, Mass., proposes to absorb the nitric oxide produced by the oxidation of ammonia in nitric acid of 60 to 70 per cent strength cooled to —40 deg. C. by the evaporation of liquid ammonia. The solution is then passed to an electrolytic cell in which the nitric oxide and nitrous acid are oxidized to nitric acid. (1,337,106; assigned to General Electric Co.; April 13, 1920.)

Acetates From Carbohydrates.—Carbohydrate material is treated with caustic soda solution to give a mixture having a specific gravity of about 1.4. To the hot causticized solution is added 40 to 50 per cent by weight of powdered quicklime. Slaking occurs with consequent evolution of heat which drives off considerable quantities of water. The product, consisting of damp porous lumps, is heated in a sealed container at 250 to 300 deg. C. for five or six hours. After cooling, the acetates may be extracted by leaching or the mass may be distilled to produce acetone. When corn glucose is treated in this manner, the product is found to contain about 15 per cent of acetates. (1,338,040; JAMES W. H. RANDALL, of Western Port, Md., assignor to Industrial Chemical Co.; April 27, 1920.)

Chlorine Liquefaction.—Chlorine gas may be liquefied at atmospheric pressure by refrigeration to approximately —35 deg. C. or at normal atmospheric temperatures by compression to several atmospheres. A compromise between the two methods appears to be the usual method of liquefaction, the chlorine being compressed about 2.23 atmospheres and refrigerated to approximately —15 deg. C. Heretofore it has been the general practice to secure the compression of the chlorine by means of gas pumps. These pumps are necessarily of very special construction and require high maintenance. CLARK T. HENDERSON, of Milwaukee, Wis., proposes to eliminate the compressor by taking advantage of the fact that chlorine is very soluble in cold carbon tetrachloride. Upon heating the solution, chlorine is evolved and in a confined space sufficient pressure is generated to liquefy the gas. Carbon tetrachloride will dissolve, at —15 deg. C., approximately 122 volumes of chlorine at atmospheric pressure and will give up approximately 100 volumes of this chlorine when heated to approximately 100 deg. C., even though the solution be under a pressure of 45 lb. per sq.in. Carbon tetrachloride is not a good solvent for carbon dioxide, air or hydrogen, the usual diluents of commercial chlorine, nor is it miscible with water, and, at any pressures within the desired working limits for chlorine liquefaction, the boiling point of carbon tetrachloride is materially higher than the temperature at which the chlorine gas is driven off. A detailed description of a continuous apparatus for applying the process indicates some of the precautions which must be taken to insure efficient heat transfer. (1,338,654; assigned to Niagara Smelting Corporation; April 27, 1920.)

Separating Wood Tars and Pyroligneous Acid.—It is the accepted practice in practically all of the wood distillation plants in this country to collect the total distillate of tar and pyroligneous acid in one large tank, from which it is pumped to a battery of settling tanks. The tar which separates in these contains 20 to 30 per cent of pyroligneous acid which is removed by distilling with a steam coil and live steam in copper stills. The condition of the remaining tar is such that further distillation for the purpose of recovering the tar oils is rendered difficult. WILLIAM E. CLIFFORD, of Memphis, Tenn., has found that the pyroligneous acid content of the tar from the settling tanks can be reduced to 2½ to 4 per cent by agitating with air at a temperature not above 85 deg. C. Treatment for two or three hours results in almost complete separation of the mixture into two layers. The tar can be successfully distilled in direct fired stills. (1,339,022; May 4, 1920.)

Carbo-Hydrogen Gas.—Carbo-hydrogen gas which is used in cutting and welding consists of approximately 85 per cent hydrogen and 15 per cent hydrocarbons of high heating value such as gases of the CH_4 and C_6H_6 series. According to JAMES R. ROSE, of Edgeworth, Pa., such a mixture is formed when methane or natural gas is fed into an electric arc through one of the electrodes. The hydrogen content can be varied by changing the rate of supply of the methane. Finely divided carbon is obtained as a by-product. (1,339,225; May 4, 1920.)

Aluminous Abrasive.—When abrasives are used in conjunction with an adhesive, such as glue, for abrasive purposes, in the form of an abrasive paper, cloth or buffing wheel, the efficiency of the abrasive depends largely upon the amount of adhesion between the grain and the glue. The amount of adhesion obtained is a function of the roughness of the surface of the abrasive. Artificial aluminous abrasives have normally a very smooth surface, and consequently, when used in conjunction with glue, do not exhibit this property of adhesion to the extent of certain abrasives having rough surfaces, such as natural emery. The smaller the crystals are, the rougher the surface will be. OTIS HUTCHINS, of Niagara Falls, N. Y., finds that the addition of strontium oxide reduces the size of the crystals in fused alumina abrasives. The charge may consist of 300 parts aluminous waste, 170 parts calcined bauxite and 30 parts strontium carbonate. (1,339,344; assigned to the Carborundum Co.; May 4, 1920.)

Sulphur Chloride.—A layer of molten sulphur is introduced into a steam-jacketed still and covered with sulphur chloride. Dry chlorine gas is passed in through a number of pipes which dip below the surface of the molten sulphur. As soon as the exothermic reaction is well under way the steam valve is closed and the temperature of the still controlled by regulating the temperature and rate of flow of water in a water jacket. The nature of the product is determined by: the depth of the $S + S_2Cl_2$ mixture in the still; the rate of flow of the chlorine; the temperature. To obtain pure sulphur monochloride, S_2Cl_2, the depth of the $S + S_2Cl_2$ is maintained equal to about 0.5 to 0.75 of the total depth of the still and the rate of flow of chlorine and the temperature are regulated until the temperature in the still head is 138 to 140 deg. C. Monochloride containing 5 per cent dissolved sulphur (such mixtures are used in the rubber trade) may be obtained by shutting off the cooling water so that the temperature in the still head rises to 225 deg. C. Sulphur dichloride will be formed when the depth of the $S + S_2Cl_2$ is decreased or the rate of flow of chlorine increased. The whole operation is preferably carried out under slightly diminished pressure. (1,341,423; RALPH E. GEGENHEIMER and MAX MAURAN, of Niagara Falls, N. Y., assignors to Mathieson Alkali Works; May 25, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 2s6 to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Glycerine.—Glycerine is obtained by fermenting sugar in alkaline solution with or without the use of a catalyst. Suitable alkaline substances are: Ammonium phosphate, ammonium carbonate, sodium phosphate, carbonate or bicarbonate, an amine, a salt of an amine, or mixtures of these. Suitable sugars are: Grape sugar, invert sugar, saccharified starch, maltose, and purified molasses, or sirup. Commercial yeast, yeast cultures or other species of yeast may be used for fermenting, and food for the yeast may be added to the liquid. Manganese sulphate and iron sulphate are suitable catalysts. In an example, 20 g. of sugar and 140 g. of disodium hydrogen phosphate are dissolved in 2 l. of water and fermented by 50 g. of commercial yeast at 30 deg. C. The liquid is afterward decolorized by boiling with animal charcoal, filtered, evaporated, and the glycerine extracted by alcohol, which is then distilled off. The yield is 12 per cent of the sugar. The fermented liquid may be purified by lime, magnesia, or iron compounds before concentration. (Br. Pat. 138,099—1919. VER. CHEMISCHE WERKE AKT. GES., Berlin. See also patents 138,328—1919 to 138,331—1919, March 24, 1920.)

Purifying Oils.—The bleaching and refining of oils, fats and other substances by means of earths, such as fullers earth, "tonsil" and "panconite," is conducted in the presence of hydrogen. In an example a strong current of hydrogen is passed through 1 kg. of rapeseed oil and 50 g. of "tonsil" gradually raised to 250 deg. C. and maintained at this temperature for 4 to 5 hr.; the mass is allowed to cool to 80 deg. C. and filtered. Oils and fats so treated are said to be particularly suitable for hardening by catalytic processes. (Br. Pat. 138,115—1919. V. SCHWARZKOPF, Bremen, March 31, 1920.)

Cellulose Compounds.—A cellulose compound suitable for use in the manufacture of non-inflammable films and in the preparation of a substitute for gelatine is prepared by treating ordinary or mercerized cellulose with a halogenized fatty acid such as chloracetic or chlorpropionic acid, in the presence of caustic alkali. In an example, cellulose is mercerized in alcoholic soda lye, separated from the excess of soda lye, treated with monochloracetic acid, and the mixture left to stand; when the reaction is complete, water is added with stirring to form a clear thick paste which is neutralized and from which the compound is afterward precipitated by the addition of alcohol. In another example, mercerized cellulose is moistened with soda lye and kneaded with the sodium salt of monochloracetic acid suspended in alcohol; when perfect solubility in water is obtained excess of liquid is removed, and the products washed with dilute alcohol, and then neutralized. The sodium salt so obtained dissolves readily in hot or cold water, forming clear viscous solutions. The free acid resembles cellulose; the copper, lead and aluminum salts are insoluble in water. (Br. Pat. 138,116—1919. DEUTSCHE CELLULOID FABRIK., Eilenburg, March 31, 1920.)

Nitrogen Oxides.—In the production of nitrogen oxides by the catalytic oxidation of ammonia by air, loss of heat is prevented and the reaction rendered self-supporting by arranging in front of a platinum gauze diaphragm, which is the catalytic material, and in proximity thereto one or more screens of metal gauze such as nickel, which is non-catalytic toward ammonia. This screen receives the heat radiated from the diaphragm or conducts the heat therefrom, and thereby acts as a pre-heater for the gases. For similar purposes another screen is arranged to the rear of the diaphragm. In addition to the use of the first screen as a pre-heater, it also serves to remove dust and to oxidize impurities such as hydrocarbons or sulphur present in the gases, which tend to poison the catalyst. (Br. Pat. 137,036—1919. C. TONIOLO, Legnano, Italy, Feb. 18, 1920.)

Alloy.—An alloy specially suitable for making castings for floats for feed water regulators and for other purposes where the articles are subjected to high temperatures and pressures is made by first preparing a white metal alloy of 61 per cent tin, 29.7 per cent copper and 9.3 per cent zinc, and afterward mixing 19.64 per cent of this alloy with 80.36 per cent of copper. (Br. Pat. 138,228—1919. A. G. MUMFORD, Colchester, March 31, 1920.)

Alkaline Earth Chlorides.—An alkaline earth sulphate, such as barytes, celestite or gypsum, is heated with magnesium chloride and coal or other carbonaceous reducing agent. Sulphuretted hydrogen is evolved and an alkaline earth chloride and magnesia are produced. The alkaline earth chloride is leached out, and the magnesia may be dissolved in sulphuric acid. When it is desired to make barium sulphate by treating the barium chloride with sulphuric acid, the hydrochloric acid evolved may be used to convert the magnesia into magnesium chloride so as to make the process cyclic. The alkaline earth sulphate may be heated with magnesium chloride without a reducing agent, at a higher temperature, but with inferior yield of alkaline earth chloride. Br. Pat. 138,486—1919. F. B. SCHOTOFF, Gwalior, India, April, 1920.)

Chrome Alum.—Chrome alum is obtained by dissolving ferrochrome in sulphuric acid, the ferrochrome being ground to a fine powder and the mixture well heated and stirred, and adding a soluble potassium salt to the resulting solution of chromic and ferrous sulphates, when pure chrome alum is crystallized out. The content of iron may be previously reduced by in part crystallizing out the ferrous sulphate. The solution of ferrochrome in sulphuric acid proceeds more rapidly in leaden vessels. (Br. Pat. 138,594—1919. G. H. HULTMAN, Stockholm, April 8, 1920.)

Detinning Process.—Tin waste materials containing tin in the form of sulphide, oxide, oxychloride, etc., are dissolved in hydrochloric acid in presence of an oxidizing agent such as niter or chlorine and heat, and the solution is then reduced to obtain stannous chloride by means of tin waste containing metallic tin, such as tinplate. The stannous chloride solution is electrolyzed, using carbon or scrap tin or iron-tin alloy as anode and sheet iron or tin as cathode. The electrolysis is started at 0.5 to 1 volt and is interrupted when the pressure rises to 2 volts. The spent electrolyte in presence of an oxidizing agent is then used as solvent for the waste tin compounds and the process is continued as above described. (Br. Pat. 138,622—1919. T. A. ELKUNE, Stockholm, April 14, 1920.)

Melting and Refining Metals.—Metals and alloys are melted and subjected to a prolonged action of a vacuum. Spongy and powdered metals may thus be converted to a coherent state. (Br. Pat. 138,648—1919. HERAEUS GES. HANAU. See also 138,651—1919. April 14, 1920.)

Synopsis of Recent Chemical & Metallurgical Literature

Effects of Strain and of Heat Treatment on Metal Structure.—The more or less slow changes in crystalline structure which take place in metals after cold work and after annealing can, according to S. NISHIKWA and G. ASAHARA, be followed by means of X-ray examination. They apply (*Physical Review*, January, 1920, pp. 38 to 45) the original method of Laue, by letting a pencil of the rays, 3 mm. in diameter, fall normally on the rolled sheet of metal (from 0.1 mm. to 0.54 mm. in thickness); the sheet is fixed about 5 cm. from the photographic plate on which spots grouped in characteristic patterns are produced.

Rolled aluminum, cadmium, copper, zinc and brass gave ill-defined patterns, but a symmetry with respect to the direction of rolling was noticeable. Silver and tin showed similar patterns immediately after rolling; when the specimens were kept at ordinary temperature for a week or two, the patterns changed into those characteristic of the annealed metals. In the case of lead and thallium no symmetry was visible after rolling, indicating either that the rolling did not distort the structure or that the crystalline recovery is rapid. The annealing was effected in an electric furnace at temperatures up to 800 deg. C. The metals, of course, differed greatly in their response to annealing. In the case of silver and tin, annealing for 30 min. at 80 deg. sufficed to obliterate all traces of the previous cold work; for copper, 2 hr. at 800 deg. was insufficient. Thallium annealed at various temperatures from 100 deg. up to 250 deg. indicated the existence of a transformation point at 227 deg. C., which would agree with observations by other methods; in tin, however, the X-ray examination did not reveal any transformation near 160 deg.

Arnold's Vanadium-Molybdenum High-Speed Steel.—In view of the excited comment in America following the newspaper announcement of a sealed patent given J. D. ARNOLD for an improved high-speed steel, a brief article by him in *The Engineer*, May 7, 1920, p. 480, will be interesting. After briefly recounting the history of Sheffield tool steels, he remarks that their steel first produced in 1892-93 containing C 0.6 per cent, Cr 4.0 per cent, W 20.0 per cent "marked the high-water mark in quality of high-speed steel." The cutting power was doubled about 1896-97 by adding to it about 1 to 1.5 per cent of Va and this composition represented the best efforts of metallurgists for many years.

"The patent taken out by the present writer in 1918 substituted, say, 6 per cent of Mo associated with a little over 1 per cent of Va, the key element of the chemical composition." This produces a steel distinctly better than the 1896-97 combination, providing the heat treatment specified is carefully carried out. The author emphasizes this point, that the heat-treatment specification is as indispensable as the chemical specification—a requirement honored largely by its neglect in America. "The functions of the key element Va appear to be: (*a*) The stabilization of the variable properties of molybdenum steel, and (*b*) the prevention of cracking during the water-hardening operation, thus securing a steel not only of notable hardness but also of remarkable thermal stability." It does not "let down" until about 700 deg. C., as compared to 300 deg. C., which ruins a carbon tool, or 550 deg. C., a temperature where low-grade high-speed steel rapidly becomes useless.

Fifty Years' Progress in Iron and Steel.—Dr. J. E. STEAD'S presidential address before the recent meeting of the Iron and Steel Institute was a very voluminous review of the industry for the past half century, covering a wide range of collateral subjects in great detail. English blast furnaces have not followed the American lead in great size and hard driving, except in one notable instance, which, as a matter of fact, did not produce iron any more cheaply than the smaller English stacks. Britishers believe that rapid driving means brief life of linings and low-silicon iron, which latter is especially undesirable for local hematite users requiring pig iron containing from 2 to 3 per cent Si. One great advance is general adoption of modern recording pyrometers for indicating blast temperature. However, despite every metallurgical effort, the general deterioration of coke quality has actually increased its consumption per ton of pig delivered. If but one-third of the heat wasted in slag could be recovered, this would reduce the fuel consumption approximately 100 lb.—a total saving of 350,000 tons coke per year, a result worthy of the best efforts of engineers.

Puddling requires fundamental reorganization. Liquid blast-furnace metal should first be dephosphorized and reduced to 1.75 per cent carbon in a tilting basic open-hearth furnace, and then transferred to a rotary furnace with permanent lining, there to be further refined by adding the exact amount of melted cinder.

Basic steel makes very slow headway, due, in Dr. Stead's opinion, to prejudice inherited from the early days when the new product was somewhat non-uniform. Acid open-hearth steel, however, is supplanting bessemer metal—not a single converter is in operation in any large works on the northeast coast. Armco iron is now being made in England by the Shelton Iron & Steel Co., and during the war was substituted for Swedish iron in the manufacture of crucible steel with most satisfactory results.

Electric furnaces increased in great number during the war, the combined available capacity now being about 300,000 tons per year. This tonnage is less than that of Germany, largely due to the fact that British furnaces melt scrap, while German furnaces refine hot basic bessemer metal. On the Tyne electric steel is being made at a price competing wth acid open-hearth, cheap power being available from coke-oven gas.

Interesting byproducts of the change in smelting practice from basic bessemer to basic open-hearth mentioned by Dr. Stead are the decreased demand for high-phosphorus puddling cinder to make high-phosphorus bessemer pig, and the decreasing amount of basic slag the farmer so tardily recognized as being the phosphorus fertilizer par excellence. Open-hearth slag has reduced phosphoric acid to about 11 per cent, and the solubility is often further lessened by the use of fluorspar or $CaCl_2$ during the heat.

Contempt Proceedings Dismissed

The following is the full text of the decision of Judge Bourquin in the contempt proceedings instituted by Minerals Separation against the Butte & Superior Mining Co.:

Minerals Separation, Ltd.
vs.
Butte & Superior Mining Co. } Contempt Proceedings

JUDGE BOURQUIN: Subsequent to the decision of the Supreme Court of the United States and pending accounting herein complainants instituted these proceedings in civil contempt based upon allegations that an account filed herein by defendant discloses it was and has been operating with methods of the patent process with less than 1 per cent of oil and contrary to the injunction. Hearing was had and it appears that at the head of the machine (see 245 *Fed. Rep.*, p. 583 for description) defendant adds to the pulp less than 1 per cent of oil but that the circulating load there entering the pulp contains sufficient oil to constitute the total 1 per cent and more. It incidentally appears that when the pulp arrives at the tail cells, at last of the machines, the oil is less than 1 per cent. Complainants contend that the oil in the circulating load is without efficacy and that both the situations aforesaid involve use of oil less than 1 per cent and are contrary to the injunction and contempt. During proceedings upon the merits, complainants urged that both these situations then existed and involved infringement, but not being vital and being rather doubtful in respects to both facts and law, the courts made no express reference or decision in respect to them. To now conclude that the Supreme Court's decision impliedly determines them favorably to complainants is mere conjecture and inadmissible. That either situation involves infringement and violation of the injunction is by no means clear. In these circumstances, having also in mind the severity and delays of contempt proceedings to the defeated party, complainants cannot be permitted to transfer the controversy from the merits to contempt. They must fully litigate upon the merits what they have half litigated so that the defeated party may have prompt review rather than suffer hardships from delays due to inability to appeal from the decision in contempt until some time after final decree in accounting. It is believed equity, patent law, discretion requires that complainants be remitted to some one of the familiar methods to secure determination upon the merits of these alleged infringements. Accordingly the contempt proceedings are dismissed.

The National Research Council Elects Officers

The National Research Council has elected the following officers for the year beginning July 1, 1920: Chairman, H. A. Bumstead, professor of physics and director of the Sloane Physical Laboratory, Yale University; first vice-chairman, C. D. Walcott, president of the National Academy of Sciences and secretary of the Smithsonian Institution; second vice-chairman, Gano Dunn, president of the J. G. White Engineering Corporation, New York; third vice-chairman, R. A. Milliken, professor of physics, University of Chicago; permanent secretary, Vernon Kellogg, professor of entomology, Stanford University; treasurer, F. L. Ransome, treasurer of the National Academy of Sciences. All of the chairmen of the various divisions of the Council have not yet been selected, but will be announced later.

New Nitrogen Fixation Plant at Syracuse

The Atmospheric Nitrogen Corporation, a company organized and incorporated in New York State with an authorized capital stock of $5,000,000 by the General Chemical Co. and the Solvay Process Co., has purchased a 60-acre tract of land near the Solvay Process Co.'s works on the western outskirts of Syracuse, N. Y.

Ground has already been broken for a new plant to manufacture 20,000 lb. anhydrous ammonia per day on a plan worked out by DeJahn, similar to the Haber process, using hydrogen from water gas, nitrogen from the air, and a suitable catalyst.

An interesting feature of the plant is the utilization of the byproducts. CO from the water gas is to be converted into CO_2, which will be used by the Solvay Process Co. as a raw material in its manufacture of soda ash, and in return, coke, a byproduct of the Solvay process, will be used to make water gas, thus closely correlating the operations of the two plants.

At present under the direction of the J. G. White Engineering Corporation of New York the company is erecting a process building, gas producer, two large gas holders, service buildings and boiler house, all of steel and brick construction, at an approximate cost of $2,500,000. Electric power will be furnished by the Niagara, Lockport & Ontario Power Co. from Niagara Falls.

Citations by Federal Trade Commission

The Federal Trade Commission has cited the following concerns for unfair competition in trade:

John Bene & Sons, Inc., Brooklyn, for compounding and selling hydrogen peroxide.

Samuel Weinberg, doing business under the name of the International Flaxol Co. at Boston, Mass. This company advertises and sells a certain commodity which it has named "Flaxol," thereby indicating that it is a derivative of flax and the equivalent of well-known products of flax, such as linseed oil, sometimes called flaxseed oil.

The United Indigo & Chemical Co., Ltd., Boston, Mass., which is engaged in the manufacture and sale in interstate commerce of dyestuffs, chemicals and other dyeing goods and products. This company is accused of secretly giving cash commissions and other rewards to employees of its customers and its competitors' customers to induce the purchase of its products.

Forty days have been given these companies to reply, after which the cases will be set down for trial on their merits.

Chicago Chemists Inaugurate Weekly Luncheon

The first regular weekly luncheon of the Chicago Chemists' Club was held on June 1 at the club quarters. Dr. A. I. Kendall, dean of Northwestern Medical School, delivered a most interesting discourse on industrial bacteria. Among the out-of-town visitors were Dr. A. V. H. Mory, of Cincinnati, and H. C. Parmelee, editor of CHEMICAL & METALLURGICAL ENGINEERING.

Budget Bill Rejected

The bill to create a national budget system, which was vetoed by President Wilson, was amended by the House to conform with the President's views and was again passed, but the Senate failed to take any action in the matter because of the opposition to the measure by Senators Harris and Reed. Anticipating the provision of budget system, the House of Representatives provided for the reorganization of its appropriations committees, forming a single committee of thirty-five members to replace the eight committees which previously had handled various parts of this work. The Smoot-Reavis resolution providing an investigation of the Federal executive departments, in anticipation of complete reorganization, was defeated in the House of Representatives by a strict party vote. The Democratic membership opposed the measure on the ground that the director of the budget should do this work, but the failure of the budget bill subsequently leaves the matter without any agency to conduct the investigation contemplated.

Byproduct Coke Plant at Birmingham, Ala., Completed

The Sloss-Sheffield Steel & Iron Co. has just completed a new byproduct coke plant at its works in Birmingham, Ala., at a cost of approximately $2,500,000. Equipment includes 120 Semet-Solvay coke ovens, buildings for byproducts, cooling pond, machine shop, engine house, stacks, offices, etc., and two 2,000-kw. electric turbines. Additional 2,000 hp. is transmitted from an electric plant about two miles away.

This plant will consume 2,500 tons of soft coal per day and yield 20,000 gal. of crude tar, 60,000 lb. of ammonium sulphate or its equivalent in liquor, 7,000 gal. of light oil, and 7,000,000 cu.ft. of marketable fuel gas in addition to that required for plant operations. About 2,000 tons of coke, or enough to operate the company's five blast furnaces, will also be produced.

Fund to Investigate Power Supply

The U. S. Geological Survey received a fund of $125,000 with authority to accept additional sums to be expended by it for an investigation of power supply throughout the Washington to Boston territory. This so-called super-power investigation contemplates a study of water-power and fuel-power developments that will undoubtedly demand consideration of byproduct coking, large steam power plants and all other possibilities. The technical, economic and resource conservation aspects of each situation will receive attention. It is hoped, therefore, that the industrial chemical possibilities of fuel-using industries will receive considerable attention in the investigation.

Great Western Sugar Co. to Build New Plant

Announcement has been made that the Great Western Sugar Co. is to erect a 600-ton plant in Weld County, Colorado, at the junction of the Union Pacific and Great Western railroads. This plant is expected to be ready for operation by next October and is similar to the Brighton plant.

This plant will have a great advantage in being situated in one of the finest sugar beet-growing sections in Colorado.

Chemical Warfare Service Continues

Under the provisions of the Army reorganization bill the Chemical Warfare Service has been continued as a permanent branch of the Army. The present provision is for 100 officers and 1,200 men, the command being headed by a Brigadier General. The appropriation bills for the coming fiscal year provide new appropriations of about $2,000,000 in addition to approximately $2,000,000 available in funds which continue for the coming fiscal period. Approximately $25,000,000 of the funds available during the past and previous years, however, revert to the Treasury unused.

All regular Army officers in this service as well as other services revert to their regular Army rank on June 30, as emergency commissions in all grades are cancelled as of that date.

Any persons contemplating application for commissions in this service must make application on form 739 before June 23.

In contrast with the continuation of this service is the fact that the construction corps was not provided for, as had been expected.

New Jersey Chemical Society Year Book

Although the New Jersey Chemical Society was organized less than two years ago, it has already assumed a position of importance among the scientific societies of the metropolitan district. Its rapid rise is best understood from a study of the recently issued year book. In this the reasons for the formation of the society are set forth, followed by a brief review of the activities and meetings of the society from Nov. 11, 1918, to Feb. 9, 1920.

In order to increase the usefulness of the volume, a chapter on chemical education in New Jersey, a list of chemical and allied periodicals available for reference in the Newark Public Library, and a classified index of chemical manufacturers and supply houses in the state have been included. The classified index also serves to indicate the extensive and varied chemical industries which form the foundation of this society and which guarantee its successful development.

Increase of Salaries for Government Technical Men Contemplated

Continuing the effort to secure better salaries for the technical services of the Government, a number of scientific men have actively participated with others in the appointment of committees to work during the summer on this problem. Two sets of committees are being provided: the first to consider classification of present employees under the system which has been recommended to Congress; and the second group of committees, one from each department, to aid in the publicity and educational work required to make the needs of the services generally known.

Internal Revenue Bureau After Alcohol in Patent Medicines

In order to minimize the consumption of patent medicines for beverage purposes where an appreciable percentage of alcohol is contained, the chemical division of the Internal Revenue Bureau is making special effort to have manufacturers of these preparations change their formulas by adding some ingredient which will discourage beverage use.

British Units to Be Used in War Department

To avoid confusion, the Secretary of War has ordered the British units of weight and measure be used as far as is practicable. The instructions issued in that connection are as follows:

"As an incident to the World War, metric units of weight measure were necessarily used in instruction and training. As a result, more or less confusion now exists as to what units should be used normally. Hereafter, the customary former units of weight and measure (including the degree Fahrenheit) will, as far as practicable, be used throughout the Army as they were before the war.

"Material and equipment now graduated in metric units will, when worn out, be replaced by articles graduated in British units in such manner as will cause all parts of a regiment or similar organization (or smaller organization when there is no regimental organization) to be provided at all times with material and equipment graduated alike.

"This order shall not be construed to prevent the utilization of metric units of weight and measure when desirable in connection with specifications and contracts, medical and scientific supplies, scientific research and developments, international meteorology, foreign maps, monographs and handbooks and similar subjects."

Hongkong Markets Shut Out American Dyes

Consul General George E. Anderson at Hongkong points out in a brief survey of the American dye industry in southern China that the United States has built up quite an extensive trade in aniline dyes and synthetic indigo during the last two years. Switzerland also shipped considerable quantities during 1919 and was one of the chief competitors in the trade.

At that time Great Britain was not exporting colors to China. Suddenly after the trade with United States was fairly well established, the Hongkong Government, at the behest of the Imperial Government in London, prohibited the importation of any but British manufactured dyes, thus shutting out American products except for reshipment. This of course gives the British dye makers a decided advantage over foreign competitors, but as they have not met the demands of the trade in the way that was expected the result has been to throw the entire dye industry into a state of uncertainty while plans are being considered to relieve the situation.

War Minerals Relief Act Amendment Fails

The war minerals relief act amendment which was intended to put war minerals claimants on the same footing as claimants seeking relief from other contract losses passed the Senate shortly before the end of the Congressional session. However, it contained an error which made it ineffective and a resolution to correct this was not considered. The bill did not receive consideration in the House of Representatives.

Japan Shipping Sugar to United States

Advantage of the high price of raw sugar is being taken advantage of by the Japanese sugar merchants to ship their surplus stock. The price of refined sugar in Japan has been 15c., but has now risen to 18c.

Consignment of Swiss Dyes Arrives

A large quantity of Swiss dyes consisting of 181 cylinders of assorted colors from Havre arrived recently. This shipment was consigned to New York firms which, it is understood, have already disposed of most of the consignment.

Although up to the present time there has been a ready market for foreign dyes, it is admitted in the trade that demand from the textile industry is disappointing. Settlement of the labor difficulties among the textile plants has not resulted in the expected increase in activity in the industry. Tightening of credits by banks, a lessening in public buying, together with the freight congestion due to strikes and difficulty in transportation of raw materials and finished products, have had a depressing effect.

Output of direct colors has been limited due to scarcity of H acid, while shortage of dimethylaniline has restricted production of basic colors. The vat color situation has somewhat improved. Two large concerns have been reported as about to market a wide range of fast colors equal to those produced by German or other foreign manufacturers. Vat yellow R is the only item that is being produced in quantity in this list at present.

Wool green S, rhodamine and patent blue are to be put on the market on a large scale as soon as general business conditions will warrant it.

Meeting of the New Haven Section, A. C. S.

The May meeting of the New Haven Section, A. C. S., was held May 14 at the Graduates Club, New Haven, Conn. After dinner at the club, a short business meeting was held, presided over by President Walter R. Hibberd. It was voted at this meeting not to publish in the *Chemiker Zeitung* results of research in chemistry by members of the society. After the meeting the members gathered at the Kent Laboratory to hear the lecture by E. M. Symes, assistant chief chemist of the Hercules Powder Co., on "The Manufacture of Dynamite and Gelatine, Including the Manufacture of Nitric and Sulphuric Acids."

This lecture was well illustrated by both moving pictures and lantern slides, and gave in a general way a good idea of the processes used and also the plants of the company.

Some idea of the tremendous force of some of the explosives manufactured was shown when 700,000 tons of rock were broken down by one blast of 120,000 lb. of dynamite at a cost of $12,500. The whole face of a cliff about 600 ft. long and 150 ft. high was blown off at one charge.

The lecture was well attended by both students and members of the society.

German Syndicate to Operate Spanish Potash Deposits

Reports are current to the effect that German interests have acquired control of Spanish potash production and that German capital and labor will work the deposits. Herr Gunte and Herr Ziervogel, two potash experts, have examined and reported on the deposits, with the result that important concessions for working these deposits are expected to be made to the German syndicate by the Spanish Government.

Swansea Patent Fuel Industry

Consul A. B. Cook reports that five patent fuel works in the city of Swansea and one plant at the sub-port of Port Talbot are now in operation. These plants are engaged in the manufacture of briquets from coal dust, a byproduct of the local coal mines.

Port statistics show reports of patent fuel from Swansea and Port Talbot as follows: 1918, 1,014,603 long tons; 1919, 1,092,803 tons; first three months of 1920, 329,402 tons.

Large quantities of tar and pitch required as a binding material are imported, as there is no production of them in Great Britain.

Personal

Prof. CHARLES BASKERVILLE, in recognition of his investigations on inhalation anesthetics, has been elected a member of the research committee of the National Anesthesia Research Society.

KENNETH E. BELL has resigned his position of research associate, research laboratory of applied chemistry, Massachusetts Institute of Technology, to accept one as chemical engineer with the Lewis Recovery Corporation of Boston.

W. F. BLEECKER of the Tungsten Products Co., Boulder, Col., has just completed an extended trip through Eastern points.

Dr. MARSTON TAYLOR BOGERT, professor of organic chemistry in Columbia University, has been appointed by President Wilson as a member of the United States Tariff Commission.

W. C. BUELL, JR., formerly engineer of tests and later chief engineer of Tate-Jones & Co., Inc., on June 1 became associated with the George J. Hagan Co., Pittsburgh, Pa., as chief engineer of the newly organized liquid fuel department.

HARMON F. FISHER has been engaged by the United States Bureau of Mines as liquefaction engineer in charge of the helium experimental plant at Petrolia, Tex.

LUCIEN H. GREATHOUSE recently resigned as assistant chemist of the Fixed Nitrogen Research Laboratory, War Department, to accept a position in experimental work with the Atmospheric Nitrogen Corporation, Laurel Hill, N. Y.

GUY C. HOWARD of the Tacoma Smelting Co., Tacoma, Wash., is visiting New York City and other Eastern points on a business trip.

A. H. KROM, assistant secretary of the American Association of Engineers, has resigned to enter business. Mr. Krom was one of the organizers of the association.

Dr. C. E. K. MEES, director of the research laboratories of the Eastman Kodak Co., Rochester, N. Y., will deliver lectures on various aspects of photographing and on the general subject of industrial research before various scientific bodies while he is in England.

H. C. PARMELEE, editor of CHEMICAL & METALLURGICAL ENGINEERING, has returned from a two months' trip to the Pacific Coast, visiting St. Louis, Omaha, Denver, Pueblo, Salt Lake City, Los Angeles, San Francisco, Portland, Tacoma and Seattle.

G. ARNCLIFFE PERCIVAL has arrived in New York City from England and expects to make a close study, from the technical point of view, of some of the larger industrial plants of this country.

The board of directors of the American Electrochemical Society at its meeting April 30 appointed the following executive committee: W. S. Landis, chairman, ex officio; J. W. Richards, ex officio; H. B. Coho, J. V. N. Dorr, C. G. Fink, Carl Hering and H. C. Parmelee.

Current Market Reports

The Non-Ferrous Metal Market

New York, June 11, 1920.—Copper market slightly weaker, with one large producer reported to be willing to sell at 17½c. on large tonnages. Large stocks are on hand. Tin has declined 5 points, to 46c., in sympathy with the London market.

	Cents per Lb.
Copper, electrolytic	18.50
Aluminum, 98 to 99 per cent	32@33
Antimony, wholesale lots	8.87½
Nickel, ordinary	45.00
Nickel, electrolytic	45.00
Tin, Straits, spot	46.00
Lead, New York, spot	.00
Lead, E. St. Louis, spot	8.50
Zinc, spot, New York	7.90
Zinc, spot, E. St. Louis	7.55

The Iron and Steel Market

Pittsburgh, Pa., June 11, 1920.

The American Iron and Steel Institute reports that in May 2,883,164 tons of steel ingots was produced by thirty companies which in 1918 made 84.03 per cent of the total output. Allowing for unreported production and computing annual rates on the basis of the number of working days, the annual rates in each month this year, in gross tons, are found to have been approximately as follows: January, 40,700,000; February, 44,200,000; March, 45,200,000; April, 37,550,000; May, 41,050,000.

The rail strike began April 1, but did not seriously affect the valleys, the lake front and Pittsburgh until about Monday, April 12. The low point in pig-iron and steel production fell at about that time or shortly after, and there was only slight recovery during April, while during May the improvement grew more and more pronounced. One may therefore conclude that a low point in production fell at about the middle of April, under 34,000,000 tons per annum, and that the rate at the close of May was nearly if not quite 43,000,000 tons. As conditions have continued to improve, it seems probable that a 45,000,000-ton rate will be regained by the end of this month.

SHIPPING CONDITIONS BETTER

Car supplies are improving at nearly all points, but at a slow rate. A few mills may now be shipping as much steel as they produce, but in general a little is still accu-

mulating, and it may be the end of the month before there is an even break. Past experience with freight congestions has been that the beginning of relief is the difficult matter, and that as small inroads are made at congested yards the improvement grows apace. It is on account of such analysis, rather than on account of the actual improvement that has occurred to date, that the steel makers have their present sanguine views as to the nearby future of transportation conditions. At the same time it is recognized that if the railroads get into normal working order they will not be able to carry much of an overload, hence it will probably require a long time to work off all the steel now stocked at mills, probably between 1,500,000 and 2,000,000 tons.

There are conflicting reports as to the relation between shipments and receipts of finished steel. At some mills the claim is made that although cars are being loaded they are not reaching destinations in fair time, which would mean that the number of loaded cars is increasing. From this it would be far from difficult to deduce that the number of empty cars available for loading would be decreasing. In other quarters, however, the observation is that loaded cars are reaching consignees much more freely than formerly, which would mean that more cars are getting into service and that practical progress is being made.

In the matter of both coal and coke there is a freer movement. Even for last week, when there was a holiday to interfere, the Connellsville *Courier* reported a slight increase in coke production in the Connellsville and lower Connellsville region. Car supplies to the Pittsburgh coal district are slightly increased.

Trends in Order Books

The Steel Corporation and the independents are getting farther and farther apart as to the size of their respective order books. May was described by independents as a dull month marketwise, and there is no doubt that it was decidedly dull from that viewpoint. On the other hand the Steel Corporation's report of unfilled obligations at the end of May shows that the corporation's bookings during the month were not simply in excess of the month's shipments but in excess of a full month's capacity. The increase was 580,719 tons, to 10,940,466 tons, the increase being equal to 44 per cent of capacity, on the corporation's own rating of 52,500 tons per working day. The month's shipments may be estimated at about 68 per cent of capacity, which would make the bookings in the month 112 per cent of capacity. Bookings similarly computed were 94 per cent in April, 124 per cent in March, 108 per cent in February and 162 per cent in January.

The unfilled obligations at the beginning of June would carry the corporation, at 52,500 tons per working day, to about Feb. 6, 1921, as an average date, or to about March 1 on the basis of a 90 per cent operation. Of course the orders are not equally distributed according to capacity of the various departments, so that such dates are merely average.

Prices of Larger Mills Firm

The independents as a whole are not booked one-half as far ahead as the Steel Corporation, though of course they have understandings with various customers to supply them with monthly quotas of steel, at prices to be set from time to time. The independents, having prices higher than those of the Steel Corporation, cannot secure orders for the late deliveries that are acceptable to Steel Corporation customers, while they cannot reduce prices without jeopardizing some of the business they now have on books. This is a principle that has always obtained in the steel trade when demand tends to fall off, but in former cases all producers were in much the same position. The mills with but little business ahead have been yielding in their prices for several weeks past, but the larger mills, booked for two to five months ahead, have been standing quite firm. Apart from the smaller mills with the leanest order books being disposed of their own accord to ask smaller delivery premiums there is another influence, that some of the mills booked for several months ahead have lately been finding it possible to make quite early deliveries at their regular prices, and this again has tended to bring down prices in the prompt market. A few weeks ago the condition was clearly defined of there being three markets, one prompt market, the moderately extended delivery market, two to five months, and the far forward market, made by the Steel Corporation. Now it can hardly be said that there are more than two markets, one for prompt or moderately early delivery and one for extended delivery, the Steel Corporation being alone in that market.

Pig Iron

Merchant furnaces can now reach almost all their customers with deliveries, and the demand for spot or prompt iron has dwindled to very small proportions, while no particular interest is aroused in late deliveries. Some furnaces now have fairly large stocks, owing to the traffic difficulties, but consumers, on the other hand, are rather bare of stocks. The market is stagnant, with no change in quotable prices, which remain: Bessemer, $43; basic, $43.50; foundry, $45, f.o.b. valley furnaces, freight to Pittsburgh being $1.40.

Semi-Finished Steel

Billets are stagnant, quotable at the last market of $60@$65, consumers being interested in deliveries of steel already ordered rather than in the making of fresh purchases. To an extent the same condition obtains in sheet bars, but there is some business from time to time. The last sale reported is of a round tonnage of bessemer bars, two or three months' delivery beginning July 1, at $75, the transaction indicating a slightly stronger tone in the bessemer market than had been assumed. Open-hearth bars are $75@$80.

Finished Steel

The merchant bar list is now split, as to early deliveries, small sizes being so scarce that a higher base, up to 4c., obtains than on moderate and large sizes, which can be done even for early shipment at about 3c.

The season cotton tie price of the Carnegie Steel Co. has been announced at $2, this being the price in lots of 3,000 bundles or more, 45 lb. per bundle, for June shipment, the carrying charge for later deliveries being 1½c. a month. One of the independents at least will follow this price, but another announces it will make no ties, and will probably await the possible development of a scarcity and bids at higher figures.

Ferro-Alloys

While small prompt lots of forromanganese might bring close to $250, delivered, the market has continued to ease off. Second half or third quarter contracts remain at $200, delivered, with little interest exhibited. Spiegeleisen remains quiet at $72.50@$75, furnace. Electrolytic ferrosilicon is stagnant, prices being largely nominal at about $78@$80 for 50 per cent and $150@$155 for 75 per cent. Bessemer ferrosilicon remains at $62.50 for 10 per cent, $65.80 for 11 per cent and $69.10 for 12 per cent, f.o.b. furnaces at New Straitsville and Jackson, Ohio.

The Chemical and Allied Industrial Markets

New York, June 11, 1920.

Changes in the chemical market during the interval have been very few and confined to the more active items of the list. Producers are limiting their output for one of two reasons; recently the theory has been advanced that a slump in the market is anticipated and the manufacturer is wary of being caught with stored supplies on hand, but the more obvious reason is the pronounced shortage of cars at the plants in which to ship the product. As a result the market remains in a strained condition with spot supplies very low and selling at a premium.

Acetic acid, glacial, 99½ per cent, is firmer at $16.50@$17.50 per cwt. than it was last week, with buying interests considerably more active. *Oxalic crystals* is in a similar position and 60@65c. per lb. is the ruling figure for spot material. The heavy chemicals have been well sustained with the exception of *potassium prussiate*, yellow, which came down slightly and is now listed at 35@36c. per lb.

for less than car lots, against 36½@37½c. of the last report. Enough has been said about the more active items on the list, so it is sufficient to say that *bleaching powder, ammonia* and *barium* products, *epsom salts* and *soda ash* remain in the same nominal position, with prices quoted varying according to the necessity of the buyer. Offerings of *potassium* and *sodium bichromate* (resale material) have been received from Japan at figures below the present market, but so far buyers have refrained from contracting because of the uncertainty as to the condition of the material and the possibility of prompt delivery.

Coal-Tar Products

As has been said frequently and truthfully, there is no activity in prices or of material changing hands in this market. Slight as it is, there is a still further decline being noticed in some quarters due to the coming summer season, but there is so very little material being offered and so few buyers at the prevailing prices that it is hardly worth while noting. On the other hand, *alpha-naphthol*, crude, is being offered at $1.40@$1.50 and refined at $1.60@$1.70, against $1.35 and $1.50, respectively, as high-water marks of the previous week. *Naphthalene* shows no signs of decline and former figures of 15@17c. per lb. for *flake* and 16@18c. per lb. for *balls* hold firm.

Waxes

The *paraffines* furnish the only interesting movement in this branch. For the past few months this movement has been steadily upward and according to many there is no break in sight, either in demand or in prices, The available stocks are so small as almost to warrant placing these waxes in a nominal position. The other grades—*carnauba* and *bees*—are plentiful with moderate orders.

Naval Stores

Predictions of an early settlement of the coastwise shipping strike, which has seriously affected this market for some time back, are heard in the trade, but as to the details of the where and when and how, nothing is definite. Small quantities of *rosin* are coming into the local market, but not nearly enough to meet requirements. All grades have been dropped to new levels which will prevail upon the resumption of normal business. *Turpentine* is available in small quantities at $1.92½@$1.95 per gal.

Vegetable Oils

Linseed has been quiet during the week with a slight drop in quotations, with $1.67@$1.70 per gal. as the prevailing figures. Crushers report business at a standstill and can see no improvement for a month at least. The rest of the list is firmly maintained, with very little activity throughout the list.

The Baltimore Market

Baltimore, Md., June 10, 1920.

The fertilizer manufacturers in this section are rapidly winding up the spring season, which has been delayed on account of labor and car shortage. There will be no intermission between seasons on account of the labor situation, and as fast as spring business is being disposed of, they are starting on fall goods.

Comparatively little interest is shown in futures, except for low grade *ammoniates*, such as garbage tankage, which is very scarce and nominally quoted at $8 per unit of ammonia, 10c. per unit of bone phosphate of lime and $1 per unit of potash, c.a.f. Baltimore. Material in good granular condition is well sold up and almost unobtainable. The demand is very heavy due to fall mixtures of *complete fertilizer* being for goods of much lower grade than for the spring season.

Phosphates

Acid Phosphate.—Producers are well sold up for June, July and August and prevailing quotations for run of pile, testing 17 to 18 per cent available phosphoric acid, vary according to tonnage and specific delivery from $18.50 to $19 per ton, basis 16 per cent A.P.A., in bulk, f.o.b. cars Baltimore, with 16 per cent grade being held at 50c. per ton higher. Actual stocks of acid phosphate which producers have on hand are very low, and all manufacturers are experiencing considerable difficulty in securing supplies of phosphate rock. While summer deliveries are usually the lowest of the year, in anticipation of augmented supplies of phosphate rock later on, October-December deliveries are obtainable at 50c. per ton below summer prices, and a fairly important business has already been booked for October-December deliveries.

Nitrogenous Materials

Blood and Tankage.—Little interest is being manifested at prevailing prices, which hold firm at the equivalent of about $8.25 and 10c. basis c.a.f. Baltimore, and manufacturers expect lower prices to rule, as the demand for tankage for feeding purposes is not brisk at present.

Nitrate of Soda.—The market for spot and nearby ranges from $3.80 to $3.85, which is below the actual cost to import, based on the market in Chile, but some resale lots which arrived too late for use during the spring season are available at 10c. to 15c. per hundred less. These, however, have not been of sufficient importance to establish a lower market.

Cyanamide.—Producers are now sold up to March, 1921, and the only material available for delivery between now and that time is resale. Resale lots for early delivery and now en route are being held at $4.75 per unit f.o.b. Baltimore, and deliveries over the balance of the year are obtainable at about $4.65 per unit.

Potassium Salts

Potash.—The Nebraska producers have disposed of their present stock and production to November, 1920, and are holding shipments beginning November and forward at $2.25 per unit f.o.b. Nebraska producing centers. There have been several arrivals during the past week of Alsatian kainit and manure salt, from which resales have been made at $2 per unit, although the most of the manufacturers are taking deliveries and storing the potash for next season's use to guard against a shortage such as existed during the early part of the past season. New prices for July and forward deliveries of the Alsatian and German products have not yet been announced.

The St. Louis Market

St. Louis, Mo., June 8, 1920.

There has been little change in the chemical market during the past two weeks and prices of most chemicals are stationary. The demand continues to be good and local producers report that a gradual resumption of normal production is taking place.

The local railroad situation shows a healthy improvement, especially for shipments to the West and Southwest. Less than carload lots are being accepted by all lines except where shipments are destined for points on connecting lines or large Eastern industrial centers. Carload shipments are moving slowly on account of the congested condition of the freight terminals. The movement of coal is being materially improved and the possibility of further curtailment of production is apparently past.

Acids.—The demand continues to be heavy and prices are unchanged. *Sulphuric* acid is quoted for carload lots at $15@$16 per ton for the 60-deg. grade and $22 per ton for the 66-deg. grade. *Oleum* is quoted at $27.50 per ton. The supply of *muriatic* acid is limited, 18-deg. grade being quoted at $21 per ton in carload lots. *Nitric* acid is quoted in carload lots at $7 per hundred for 36-deg., $8 for 38-deg., $9 for 40-deg., and $10 for 42-deg.

Sodium Bisulphate. — Supply very limited; price unchanged at $4 per hundred.

Phenol.—Demand good and supply plentiful, due to local firm disposing of surplus Government stock. Quotation unchanged at 12c. per lb., in carload lots.

Zinc Oxide.—Local supplies are low and producers are booking orders for third quarter delivery. Quoted at 10c. per lb. in large lots.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots		Less Carlots	
Acetic anhydride	lb.			$0 62	$0 65

Para-toluidine	lb.	.65	.75
Phthalic anhydride	lb.	.12	.20
Phenol, U. S. P., drums (est.) (240 lb.)	gal.	2 00	3 00
Perilin	lb.	4 25	4 50
Resorcin, technical	lb.	5 25	6 75
Resorcin, pure			

Salicylic acid, tech., in bbls. (110 lb.)	lb.	$0.50	—	$0.52
Salicylic acid, U. S. P.	lb.	.50	—	.60
Salol	lb.	.90	—	1.00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25	—	.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.28	—	.32
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.36	—	$0.39
Beeswax, refined, light	lb.	.39	—	.40
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1. (nominal)	lb.	1.00	—	1.05
Carnauba, No. 2, regular (nominal)	lb.	.85	—	.88
Carnauba, No. 3, North Country (nominal)	lb.	.43	—	.44
Japan	lb.	.21	—	.22
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09½	—	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11½	—	.12½
Paraffine waxes, refined, 128-130 m.p.	lb.	.13	—	.13½
Paraffine waxes, refined, 133-135 m.p.	lb.	.15½	—	.16½
Paraffine waxes, refined, 135-137 m.p.	lb.	.17½	—	.18½
Stearic acid, single pressed	lb.	.25	—	.26
Stearic acid, double pressed	lb.	.26	—	.27
Stearic acid, triple pressed	lb.	.28	—	.29

NOTE—Quotations on paraffine waxes are nominal

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.80
Pine oil, pure, dest. dist.	gal.	1.60
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.50	—	$18.00
Rosin E-I	280 lb.	18.50	—	19.75
Rosin K-N	280 lb.	20.00	—	21.00
Rosin W. G.-W. W.	280 lb.	21.25	—	23.00
Wood rosin, bbl.	280 lb.	17.00	—	17.00
Spirits of turpentine	gal.	1.90	—	1.92
Wood turpentine, steam dist.	gal.	1.75	—	1.85
Wood turpentine, dest. dist.	gal.	1.45	—	1.55
Pine tar pitch, bbl.	200 lb.	.....	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	15.00
Retort tar, bbl.	500 lb.	15.00	—	15.50
Rosin oil, first run	gal.	.87	—	.89
Rosin oil, second run	gal.	.89	—	.92
Rosin oil, third run	gal.	1.04	—	1.05
Rosin oil, fourth run	gal.	1.12	—	1.12

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.40
70-72 deg., steel bbls. (85 lb.)	gal.	.38
68-70 deg., steel bbls. (85 lb.)	gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.29

Crude Rubber

Para—Upriver fine	lb.	$0.37½	—	$0.38
Upriver coarse	lb.	.28¾	—	.29½
Upriver caucho ball	lb.	.30	—	.30½
Plantation—First latex crepe	lb.	.38	—	.39
Ribbed smoked sheets	lb.	.38¾	—	.39
Brown crepe, thin, clean	lb.	.37	—	.38
Amber crepe No. 1	lb.	.....	—	.40

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.18½	—	$0.20
Castor oil, AA, in bbls.	lb.	.20	—	.22
China wood oil, in bbls.	lb.	.22½	—	.23½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.17½	—	.18½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.18½	—	.19½
Corn oil, crude, in bbls.	lb.	.17½	—	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.15½	—	.16
Cottonseed oil, summer yellow	lb.	.19	—	.19½
Coteonseed oil, winter yellow	lb.	.21	—	.22
Linsed oil, raw, car lots (domestic)	gal.	1.67	—	.....
Linseed oil, raw, tank cars (domestic)	gal.	1.62	—	.....
Linseed oil, boiled, car lots (domestic)	gal.	1.70	—	.....
Olive oil, commercial	gal.	3.10	—	3.25
Palm, Lagos	lb.	.12½	—	.13½
Palm, bright red	lb.	.13	—	.13½
Palm, Niger	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.15½	—	.16½
Peanut oil, refined, in bbls.	lb.	.22	—	.24

Talc, talcum powder grade, California	ton	20.00	—	35.00
Talc, imported	ton	60.00	—	70.00

Refractories

Following prices are f.o.b. Works:

Chrome brick	net ton	$75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Fire clay, f.o.b. Baltimore	net ton	5—7
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	85-90 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.17	—	.18
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon	lb.	.18	—	.19
Ferro-manganese, 70-80% Mn.	gross ton	200.00	—	250.00
Spiegeleisen, 16-20% Mn.	gross ton	72.50	—	75.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.25	—	2.75
Ferro-silicon, 50%	gross ton	80.00	—	90.00
Ferro-silicon, 75%	gross ton	150.00	—	160.00
Ferro-silicon, 10-15%	gross ton	60.00	—	65.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	.90	—	1.10
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	7.00	—	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50	—	7.75

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3 f.o.b. Atlantic Seaboard	unit	$0.70	—	$0.85
Coke, foundry, f.o.b. ovens	net ton	15.00	—	15.50
Coke, furnace, f.o.b. ovens	net ton	14.50	—	15.00
*Petroleum coke, refinery, Atlantic seaboard	net ton	.....	—	24.00
Fluor spar, gravel, f.o.b. mines	net ton	25.00	—	30.00
*Fluor spar, acid grade, lump, f.o.b. Tonuco, Mex.	net ton	30.00	—	45.00
*Fluor spar, acid grade, ground, f.o.b. Tonuco	net ton	55.00	—	65.00
Manganese ore, 45% Mn and over	unit	.80	—	85
Manganese ore, chemical (MnO_2)	gross ton	80.00	—	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.85	—	.....
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00	—	.....
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50	—	7.50
Uranium oxide, 96% per lb. contained U_3O_8	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	12.00	—	14.00
Vanadium Ore per lb. of V contained	lb.	1.00	—	3.00
Pyrites, foreign, lump, per unit of S contained	unit	.16½	—	.....
Pyrites, foreign, fine, per unit of S contained	unit	.16½	—	.....
Pyrites, domestic, fine, per unit of S contained	unit	.16	—	.17½
Ilmenite, 52% TiO_2, per lb. ore	lb.	.02	—	.....
Rutile, 95% TiO_2 per lb. ore	lb.	.20	—	.25
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75	—	3.00
Zircon, washed, iron free	lb.	.10	—	.....
Monazite, per unit of ThO_2	unit	42.00	—	.....

EAST CLEVELAND (Cleveland P. O.)—The Natl. Lamp Co. of the General Electric Wks., Nela Park, has awarded the contract for the construction of a 1-story, 55x110-ft. laboratory at Nela Park, to the Heller Bros., Youngstown. Estimated cost, $100,000.

ELYRIA—H. A. Beck, Dir. of Pub. Serv., will receive bids until June 21 for the construction of a filtration plant, substructures and appurtenant works, including coagulating basin, filtered water reservoir and rapid sand filter banks, etc. Noted April 13.

HURON—The Universal Steel Co., 833 Schofield Bldg., Cleveland, has purchased a site and plans to build a 2-story, 78x[illegible]-ft. tube and conduit mills, to equip. Estimated cost, $400,000. F. W. Mettler, engr.

IRONTON—The Sheridan Coal Co. plans to construct a brick manufacturing plant including ovens, kilns, pulverizing machinery, etc., at Sheridan, near here. Estimated cost, $[illegible].

LIMA—The Bd. Educ. will receive bids until June 15 for the construction of a 2-story, 82x124-ft. high school. A chemical laboratory will be installed in same. Estimated cost, $123,000. McLaughlin & Hulsken, Savings Bldg., archts.

STOUTSVILLE—The city received bids for the construction of a sewage disposal plant for school building from the Stout Bros., $5,150; Taylor & Linn, Zanesville, $5,500.

XENIA—The city will soon award the contract for the construction of a 1,000,000-gal. water purification plant, etc. Kenyon Riddle, city mgr.

Oklahoma

PURCELL — The Legislative Council have engaged Johnson & Benham, consult. engrs., 150 Nassau St., New York City, to prepare plans and submit estimates for the construction of an impounding reservoir, intake works, modern filtration and sterilization plant.

Oregon

PORTLAND—The Pub. Dock Comn. will soon award the contract for furnishing $75,000 worth of phosphate handling machinery and 3,900 ft. of 30-in. conveyor belting for same. G. B. Hegardi, engrs.

Pennsylvania

McKEESPORT—The Columbiana Fdry. Co., House Bldg., Pittsburgh, is building a 100x300-ft. foundry and a 40x140-ft. office and pattern shop. Estimated cost, $250,000.

Rhode Island

PAWTUCKET—The Pawtucket Hosiery Co., 107 Rand St., Central Falls, has awarded the contract for the construction of a 1-story, 32x75-ft. textile mill, to the Humes Constr. Co., 76 Dorrance St., Providence. Estimated cost, $15,000.

South Carolina

COLUMBIA—The Colon Ry. Gas & Electric Co., Arcade Bldg., plans to expand present gas plant by building tanks, etc., to provide for several hundred thousand more cu.ft. of gas. Estimated cost, $400,000. J. G. White Eng. Corp., 43 Exch. Pl., New York City, engr.

Tennessee

MEMPHIS—The Memphis Steel & Iron Works plans to build a rolling mill in the northern part of the city. Equipment will be installed in same. Estimated cost, $300,000. J. E. Conley, pres.

Texas

BRECKENRIDGE — The Breckenridge Oil & Refining Co. is having plans prepared for the construction of an oil refinery to turn out gasoline, kerosine, lubricating oils and other refined oil products. The plant will have a 1,000 bbl. daily capacity. Estimated cost, $300,000.

FARMERSVILLE—The Bd. of Directors of the Farmersville Sewer Co. will soon award the contract for the construction of sanitary sewer lines and 2 sewage disposal plants. J. E. Worden, treas.

FORT WORTH—The Physicians & Surgeons Hospital is having plans prepared for the construction of a 4-story hospital on B'way Blvd. Complete surgical equipment will be installed in same. Estimated cost, $300,000. Sauguinet & Staats, 1st Natl. Bank Bldg., archts.

WHITESBORO—Harry Reast, secy., will soon award the contract for the furnishing of all labor and material for the construction of a sanitary sewer system and disposal plant.

Vermont

BRATTLEBORO — The C. F. Church Mfg. Co., Willimansett, Mass., has awarded the contract for the construction of three buildings including a 1-story main building, 1-story dry kiln, etc., to E. F. Carlson Co., 244 Main St., Springfield, Mass. Estimated cost, $80,000.

Virginia

RICHMOND — The Virginia Carolina Rubber Co., Real Estate Exch. Bldg., will soon award the contract for the construction of 50x240-ft. building for the manufacture of tires, etc. Estimated cost, $15,000. J. T. Waddell, engr.

WINCHESTER—The Harloe Tire Co., St. James Hotel, Wash., D. C., plans to construct a building. Estimated cost, $150,000. Address Mr. King.

Wisconsin

FOND DU LAC—The Bd. Educ. is having plans prepared for the construction of a 2-story junior high school. A chemical laboratory will be installed in same. Estimated cost, $300,000. Childs & Smith, 64 East Van Buren St., Chicago, archts.

MADISON—The State appropriated $25,000 for the installation of additional toilet facilities on the state fair grounds, the construction and equipment of necessary buildings, a septic tank and equipment and for the construction of necessary extensions of water mains and sewers.

MADISON—The state appropriated $90,700 for the construction and equipment of the upper three floors of the west wing of the Chemistry Building here.

MANITOWOC—H. Zannacker & Sons, 923 Washington Ave., will receive bids until June 18 for the construction of a 3-story, 50x64-ft. dry cleaning building on 18th St.

WATERLOO—The village will receive bids until July 1 for the construction of sanitary sewers and septic tanks. W. J. Higgins, clk.

Ontario

HAMILTON—The Mercury Mills, Ltd., has awarded the contract for the construction of a 4-story, 50x260-ft. dye house on Cumberland Ave., to W. H. Cooper, Clyde Block. Estimated cost, $150,000.

Quebec

LAPRAIRIE—The Interprovincial Clay Products Co. of Canada, Ltd., a subsidiary company of the Interprovincial Brick Co., will soon receive bids for the construction of a plant and the installation of equipment.

MONTREAL—The Barrett Mfg. Co., 2021 St. Hubert St., has awarded the contract for the construction of a 2-story, 38x54-ft. roofing manufacturing building on Boyer St., to the Sheaver Co., 277 St. Patricks St., at $18,500. Noted April 14.

MONTREAL—The Canadian Con. Rubber Co., 201 Inspector St., has awarded the contract for the construction of a 100x150-ft. rubber goods factory at Guy and St. James St., to Lockwood, Greene & Co., 285 Beaver Hall, at $100,000.

OTTAWA—The Gatineau Co., Ltd., plans to construct pulp and paper mills, 3 dams, etc., in the Gatineau Valley Dist. Estimated cost, $30,000,000. C. B. Thorne, Montreal, engr.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its twelfth semi-annual meeting as follows: June 28 and 29 will be spent in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE FOREST PRODUCTS LABORATORY will hold its decennial celebration at Madison, Wis., July 22 and 23, 1920.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INSECTICIDE AND DISINFECTANT MANUFACTURERS' ASSOCIATION will hold its midsummer meeting at Boston, July 15 and 16.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE ILLINOIS MINING INSTITUTE will meet in Chicago, June 23 to 26.

THE STEEL BARREL MANUFACTURERS' ASSOCIATION will meet in Chicago, June 24.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Industrial Notes

SIDNEY CORNELL, chemical and industrial engineer, has moved his office from 1 West 34th St. to 80 Maiden Lane, New York City.

METALLURGICAL RESEARCH ENGINEERING Co. has moved its office to 427 Reaper Blk., corner of Clark and Washington Sts., Chicago, Ill.

INDIANAPOLIS CHAMBER OF COMMERCE BUREAU OF INDUSTRY has prepared a large map of the City of Indianapolis showing vacant factory sites that are available, street-car service, transportation and all physical features that enter into the selection of industrial sites.

THE U. S. COPPER PRODUCTS CORP. of Cleveland, Ohio, announces the opening of a New York City office at 1123 Broadway, for the sale of seamless brass and copper tubes. This branch will be under the management of Herbert Gnad.

THE GILLESPIE EDEN CORP. is the name of the consolidation of the Gillespie Manufacturing Co., the Gillespie Motor Co., the Gillespie Foundry Co. and the Brokaw-Eden Co. Executive offices are at 50 Church St., New York City.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., announces that the Chicago offices have been removed from the People's Gas Bldg. to the company's own building, 323 No. Michigan Ave. H. L. Dawson is manager.

THE GENERAL CERAMICS CO., 50 Church St., New York City, has established an engineering department at 145 West 45th St., New York City. P. C. Kingsbury is chief engineer of this branch office.

THE STEARNS-ROGER MFG. CO., Denver, with which W. C. Graham of the Great Western Sugar Co. and W. G. Haldane, formerly president of the Colorado School of Mines, are associated as consulting engineers, has taken a contract for the improvement of the processes and practice of the American Potash Co. at Antioch, Neb. The Stearns-Roger organization is one of the few that have specialized in the production of potash from lake waters, and has succeeded in solving some of the difficult problems encountered in this comparatively new industry.

THE MERRILL CO., of San Francisco, has transferred the manufacture of the Nordstrum valve from San Francisco to the plant of the Swenson Evaporator Co. at Chicago.

THE WISHNICK-PUMPEER CHEMICAL CO. has been organized with offices and warehouse at North Pier Terminal, 365 East Illinois St., Chicago, for handling chemicals, oils and colors. The members of the firm are Robert Wishnick, David Pumpeer and Julius Pumpeer, all formerly connected with A. Daigger & Co., Chicago.

The Spirit Of the West

IN SPITE of much of the unimpressive "boosting" that is indulged in by the estimable inhabitants of the cities on our Pacific Coast, a visitor among them is constrained to admire the ingenuity, resourcefulness and energy displayed in their industrial and commercial life. One may not be deeply moved by stories of the rising values of real estate, but he cannot escape the conviction that potential wealth in water power and raw material exists in greater concentration in that western empire than in any other part of the country. Handicapped though it may be now by sparsely settled areas, light local demand for its own wonderful resources and immense distances from present domestic markets, this region is nevertheless the one toward which industry and commerce in the United States must ultimately grow.

And not to meet domestic needs alone, but to supply foreign markets as well; for despite the fact that the people of the United States have, or had before the war, little or no international sense and vision, dwellers on the Pacific Coast have a lively sense of international trade and world business. Looking east they face their own country, but to the west is another world teeming with potential consumers of the products of our civilization, and prolific in natural and artificial commodities that will find a ready market here. Like the Atlantic Coast of our country, the Pacific has a double outlook and is just beginning to develop its possibilities.

Its industry is growing impressively. Climate and cheap hydro-electric power developed by the municipality are responsible for the recent location of an immense rubber factory in Los Angeles. Harbor and shipping facilities are making of San Francisco the great port of the Pacific Coast. Portland, though an inland city, is developing an export and import trade; while the two cities on Puget Sound, Seattle and Tacoma, are centers of world-wide trade in edible oils and copper. Notable is the fact that fixation of nitrogen by the arc process is practiced only in our great Northwest, where water power is cheapest, and electric smelting of iron ores is giving promise of developing there into a stable industry.

In short, engineering and technical developments are the substantial things that impress the visitor, even though they are not most often "boosted." But even the "boosting" can be condoned on the score that it creates and supports a spirit of civic loyalty too often lacking in Eastern communities, and is in some degree expressive of that Western hospitality that is as large as the great out-of-doors and which does not find its counterpart elsewhere in the country.

President Signs Water-Power Bill

ANNOUNCEMENT was made at the White House on the 18th inst. that the President had signed the water-power bill on the 11th, within ten days from the time it was delivered to him. The provisions of the bill, outlined elsewhere in this issue, are accordingly the law of the land. In spite of the fact that it was necessary to support the legality of the President's act by a technical interpretation of the Constitution by the Attorney-General, it is not believed that this will have any effect in delaying actual development of water power. Money is now the most necessary item. Had Secretary PAYNE been less solicitous regarding possible damage to our national parks through water-power development, the delay need not have occurred and the bill could have been signed before Congress adjourned. Mr. PAYNE'S reported anxiety regarding the parks was unimpressive and his eleventh-hour conversion unconvincing. One could have wished that Mr. LANE were still Secretary of the Interior. No one had a higher appreciation of our national parks than he; but that did not warp his judgment of the value of water-power development.

Developments in Flotation Litigation

ELSEWHERE in this issue we publish two items relative to the litigation between Minerals Separation, Ltd., and the Miami Copper Co. One relates to a motion by the defendant in the United States District Court at Wilmington to dismiss the petition of the plaintiff seeking to punish the defendant for contempt of court. The other announces the order of the United States Circuit Court of Appeals, Philadelphia, refusing to grant the Miami company's petition to reopen the case to admit newly discovered evidence.

It is a mere coincidence that these two items appear in the same issue, as they are not directly connected with each other. There is, however, a certain relation, since the Circuit Court of Appeals virtually remands the subject matter of the Miami petition to the accounting proceedings before the Master, whereas the petition of Minerals Separation, Ltd., seeks to remove questions at issue from the accounting.

Unfortunately the original decision of the Circuit Court of Appeals in the Miami case stops short of what is, for the general mining public, *the* important question, namely, whether the use of the pneumatic cell itself is, or is not, an infringement of patents. The reopening of the case would have permitted a more prompt adjudication of the question in its broadest sense. However, in the last analysis the determination of this point by the Master will have the same effect, as it will then come by appeal before the same court.

Where Are The Chemists?

SURPRISE was expressed by one delegate to the organizing conference of the Federated American Engineering Societies that the chemists were not more largely represented on the floor. Invitations were sent to a long list of engineering and allied technical associations, and yet the American Chemical Society—the most numerous body of chemists, more or less technical—did not send deputies. However, the matter was briefly dismissed by the statement that chemists are not engineers.

Holding the opinion that the Chemical Society should have been represented, it is not so easy to excuse absence in that manner. Risking the chance of tedium, a few thoughts on the relationships of the numerous engineers served by CHEMICAL & METALLURGICAL ENGINEERING will be advanced.

"Engineering" has been defined by enthusiasts to be as all-embracing as the official statement of scope of the Bureau of Standards: "The establishment of standards of measurements, constants, quality, performance and practice"! A like blanket definition is that which regards engineering as "the art of organizing and directing men and of controlling the forces and materials of nature for the benefit of the human race." Evidently a sailor and a surveyor are both included—the wide reaches of engineering includes Generals GORGAS and GOETHALS!

Obviously a more restricted meaning corresponds with usage, despite the enthusiasts. An engineer is rather an applied physicist, he who understands the laws of heat, electricity, light, sound, dynamics and statics and can make them useful to man in structures and machines. In this way the sailor and General GORGAS—indispensable though they be—are evidently and properly not classified with the surveyor and General GOETHALS.

Now, is a chemist, "versed in the science of the composition of substances and their transformations," an engineer in this sense? If the chemist is a scientist—one intimate with the systematic knowledge of his subject—he evidently is not called an engineer, and rightly so; and it would be no less than a calamity to revise educational methods so that nearly all the students would graduate chemical engineers, to the exclusion of chemists. On the other hand, if he is more the artist—one whose knowledge is made efficient and useful to his neighbors by skill—then he would be welcomed into their fraternity by all engineers. Dr. STIEGLITZ, evidently, is a chemist primarily, and in no sense an engineer; he is a scientist. Dr. LITTLE, on the other hand, is an engineer primarily, even though well versed in chemistry—he is skilled in the art and science by which the properties of matter are made useful to man through structures and machines. "Properties of matter" is evidently a broad term—so is engineering a broad profession. Both are subdivided by using qualifying adjectives—an electrical engineer applies electrical properties of matter to useful ends, a chemical engineer applies chemical properties of matter to useful ends, a metallurgical engineer applies chemical and physical properties of metals to useful ends.

No apology is needed, then, to most of our readers for devoting much space to the Federated American Engineering Societies, whose object is to further the interests of the public through the use of technical knowledge and engineering experience as applied to political economy, and to consider and act upon matters common to the engineering and allied technical professions. It seems most fit that engineers—a group of educated men distinguished from scientists principally because the engineer applies science for human benefit—it seems most fit that they should organize to further, collectively, the interests of the public.

By the same token, it seems incongruous that the American Chemical Society should lag behind the lead of the American Electrochemical Society and the American Institute of Chemical Engineers in its interest in the Federation. It is true that a large proportion of its members is interested in chemical research, chemical theory, or chemical activities very distantly related to industry—but so are numbers of men in the smaller Electrochemical Society. On the other hand, both associations have many members who are distinctly engineers, and many more members whose work—even though it be of the humblest routine variety—is intimately connected with industrial and engineering enterprise. Does not the American Chemical Society publish a *Journal of Industrial and Engineering Chemistry?* Evidently the interest in the society is quite strong to warrant a publication entirely separate from its scientific annals. Then why do they not act like engineeers and electrochemists? The work ahead is big enough so that there is room for all engineers and allied and associated spirits, and hard enough to need all possible shoulders to the wheel. If the American Chemical Society desires to function in public affairs—and we know it has been urging individual chemists to do so—then why has it not embraced this opportunity to join in the creation of a body for that very purpose?

Synthesis and Analysis Of Engineering Formulæ

OF RECENT years the mathematical laboratory has come to be as thriving a workshop as any other place set apart for scientific investigations. As long as bridges and great structures have been designed, the study of lines of force, as theoretically developed in the science of statics and dynamics, has been of fundamental importance. Engineering of every kind has been dependent on the mathematical development of the pure science with which it was concerned. In a way, next to being able to apply known formulæ in an intelligent manner, the greatest asset of an engineer is to be able to synthesize new ones himself or reverse the operation and analyze any that may be presented to him by others.

In this issue we have a mathematical development that should have an important bearing in a number of directions in technology. It will have to be further developed before it will give the distillation engineer a full set of implements for the solution of his problems, but as it now stands it fills a very large gap that has prevented any considerable progress in the direction of applying mathematics to the consideration of saturated vapors. It may now be expected that the lesser devious ways of partial pressures and Raoult's law may be put on a practical mathematical basis, and give the much-needed formulæ for the calculation of distillation problems.

In connection with the formulæ developed by Mr. WILLIAMSON and the method given at the conclusion of the article for facilitating calculations, it should be mentioned that this year is the three hundredth

anniversary of the logarithm scale, which was invented by GUNTER, an engineer, only six years after NAPIER had conceived the idea of logarithms. Many years passed before the slide rule was brought out and still many more before the alignment chart was developed to give a convenient means of using GUNTER'S log scale. GUNTER used a draftman's compass. In all probability there is as much opportunity today for us to improve on the application of this scale as there was in GUNTER'S time. It is hoped that every reader has at least a small corner in his mind for his mathematical laboratory and that he does not neglect to use it in the study of either pure or applied science.

Organized Labor And the Public

BEFORE President WILSON'S first Industrial Conference last October, it was remarked in some quarters that organized labor was on the defensive, and would have to occupy that attitude at the coming conference. No such attitude was taken, however, by Mr. GOMPERS and his associates and the conference broke up.

A good bit of water has passed the mill since that time. The public has been taking more and more interest in the subject of organized workers and unorganized workers and is rapidly coming to recognize its numerical superiority. Mr. GOMPERS has helped the public to an appreciation of the situation and of his own position in many ways, and particularly so by his delayed attempt to answer Governor ALLEN'S question whether in an industrial dispute the public has no rights. Mr. GOMPERS had to take time to reflect and after he had taken the time—we do not answer for the reflection—he said a number of things not precisely to the point. One that is readily recalled was in substance that every worker must get at least $2,500 a year first.

The obvious rejoinder to Mr. GOMPERS' denial of the public having any rights in an industrial dispute is to inquire how it would be if the shoe were on the other foot—if it were a case of a lockout instead of a strike. Mr. GOMPERS should reflect that the ins sometimes become the outs. The public certainly would not stand for an unreasonable lockout, nor is there any prospect of any large employer at any time undertaking an unreasonable lockout. One wonders—or rather one does not need to wonder—what the attitude of the people would be if a large trolley company were to discontinue its service for a while in order to induce its employees to work for lower wages.

There is likely to be a new reaction in the public mind. The doctrine has been preached everywhere that the "vicious circle" of advancing wages and advancing cost of living, turn about, will get us nowhere. The public has not yet reflected sufficiently upon the proportions of the total number of workers that are, respectively, organized and unorganized. The proportions are approximately 10 per cent and 90 per cent, and for the substantial accuracy of these figures ample proof can be furnished by intelligent interpretation of the last census report showing those engaged in gainful occupations, with allowance for increase in population meanwhile, and the number, not of union workmen, but of the membership claimed by the labor unions.

There will be an important mental reaction when the public comes more fully to consider the proportion of one organized worker out of every ten, and the dictum that has been preached that there is a vicious circle. The alleged vicious circle would get us nowhere, but if one-tenth of the population attempts to better itself at the expense of the ten-tenths, being willing to pay its one-tenth of the tax by virtue of the nine-tenths it escapes, then there is another case altogether.

The public is also coming to a clearer realization of the psychology of the labor unions, that in order to keep things going the leaders must be continually promising the rank and file additional things. There is no stopping. The leaders cannot thrive on past accomplishments, but must continually suggest new goals to be reached. In other words, the union leaders can never get things fixed up satisfactorily, and when the public realizes, as perhaps it will, that this is the situation, it is likely to exclaim "What's the use!" Such a reaction, also, would greatly help in putting things where they belong.

Horse Thieves Among Chemists

IN THE chemical profession as elsewhere there are unfortunately a few unethical persons who take advantage of the general high standing of the collective body for personal aggrandizement or dishonest financial gain. From very early times it has been the desire of scientific men to force such members without the pale.

It is related in the biographical writings of Sir HENRY ROSCOE, as told recently at the Chicago Chemists' Club, that a certain chemist working in a research laboratory obtained exact results as to the atomic weight of the metal under consideration. Sodium, for instance, showed an exact weight of 23. The chief, becoming suspicious, gave him for test a mixture of potassium and sodium, telling him it was sodium. The atomic weight was still proved to be 23. Whereupon this chemist was discharged and, affiliated with the Baptist church, became acquainted with the pastor's servant. One Sunday when she was alone in the house, he bound and gagged her, lifted the family plate and fled to America. He was pursued by the authorities, who located him in the West, but alas, too late, as he had just been hanged for stealing horses.

The procedure is applicable in these times. If the professional career of technical immoralists and pirates is not brought to an end through slow workings of the social laws, a little "Western justice" administered by political action in technical societies will not come amiss.

How Consulting Chemists Secure Clientele

A MANUFACTURING chemist once asked, "How do these consulting chemists get business?"

In Chicago there lives a genial chap, gray with years, young in mind, who prospers because he is loved by all who know him. Aside from being a chemist he is a soul of large understanding, a man among men. He lives in his work and delights in the association of those who come within his ken. He is ever ready to assist the younger ones in the pursuit of paths chemical. He's a regular fellow in his own quiet way. He follows ideals, *not* dollars. It is a privilege to enter his office.

So business just comes into his office, for men trust him. The answer is just there—the human touch by an honest hand is the best business getter.

Readers' Views and Comments

Effect of Insulation on Resistor Temperatures

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 661 of your issue of April 7, you presented an abstract of an article by W. A. Gatward on Nickel-Chromium Alloys. Referring to wire heating-elements of electric furnaces, the abstract says:

"Experience shows that the presence of a cold body near a certain part of a heating element causes that portion to advance slightly in temperature. If the wire possesses too large a coefficient (temperature coefficient of resistance), this will cause that *portion* to become increasingly hotter until it melts."

The presence of a cold body near a certain part of a heating element can only cool that part, and there is not in such instance any paradox.

However, sudden cooling of a sufficiently large part of the heater will frequently allow the heating current to increase to a value which will burn out another part of the heater. I have often observed this, and the reason for such an occurrence is clear. Of course it can happen only if the element has a positive temperature coefficient of resistance.

A close reading of Mr. Gatward's paper makes it clear that what he had in mind is the local action of a heat insulator, for the presence of an insulating body near a portion of the heater will at times cause the part to burn out—and the insulator may be at first a cold body. That he was not strictly quoted may be inferred from the following verbatim extract from his paper:

"The development of hot spots is very much affected by the temperature coefficient. Another effect of high temperature coefficient is as follows: Imagine a heating unit wound around a muffle as generally used in electric laboratory furnaces. The heating unit is a continuous piece of wire. Suppose that the furnace is operating at 1,800 deg. F. and we place on the floor a fireclay brick. The fireclay brick immediately banks up the flow of heat and the temperature of the wire under the brick rises. This is not a theory but a fact, and the rise is very serious. As the wire under the brick gets hotter its resistance increases. Since the current is the same in all parts of the heating coil, the heat developed, I^2R, will be greater on the floor than on the sides and top. Of course this phenomenon is cumulative and is the actual cause of many burn-outs in industrial devices. The higher the temperature coefficient the more serious this will be."

Mr. Gatward would possibly have been more clear if he had said that by placing a firebrick (or other heat insulator) near the heater, local heating occurs. In this way the editor would not have substituted "cold body" for Mr. Gatward's "fireclay brick." It is not that the brick is cold but that it will not conduct heat very rapidly which is the essential quality.

I had thought that some of your readers would be misled by your abstract which states that "presence of a cold body . . . causes . . . advance in temperature," and have commented on this point because the statement is closely related to the requisites for good furnace construction. One of these is that great care must be taken in applying insulation uniformly, especially when the furnace is to be operated at highest safe temperatures. C. O. FAIRCHILD.

Washington, D. C.

A Rapid Method for the Analysis of Monel Metal

To the Editor of Chemical & Metallurgical Engineering

SIR:—May I make a further suggestion on Mr. Covitz's article which appeared in your magazine, issue of Jan. 7, 1920, p. 31, in regard to the "Rapid Method for the Analysis of Monel Metal"?

In determining the nickel contents, he suggests the usual precipitation with dimethylglyoxime, which in my estimation and experience is a slow process of filtering the resultant precipitate, besides the reagent being an expensive one at the present time.

For the copper content, I plate out my copper from the silicon filtrate by Mr. Covitz's plan. Another weighed sample is dissolved in nitric acid and then driven off with concentrated sulphuric acid, using 10 c.c. Take up with water and heat if necessary to get into solution, cool, then neutralize with ammonium hydroxide. Add about 40 c.c. in excess, also introduce 5 g. of ammonium sulphate. Have bulk of solution about 200 c.c. Connect up to the plating apparatus and proceed to plate out the copper plus the nickel, using three amperes and a revolving cathode whereby one obtains all the copper deposit first, then the nickel, without any interruption whatsoever. The operation of electrolysis usually consumes about one hour.

Strange as it may seem, the nickel does not start to plate until all the copper has been deposited. The combined weights of nickel and copper minus the weight of the copper deposit obtained from the silicon filtrate will, of course, give the nickel content.

The writer has taken copper and nickel salts, also samples of various nickel and copper percentages, and has obtained excellent results by following the scheme as outlined.

If the sample contains cobalt, a correction must then be made, although the writer has never encountered it in monel metal. PAUL W. C. STAUSSER.

Detroit, Mich.

Prosperity of Belgian Artificial Silk Industry

Some Belgian artificial silk works are enjoying prosperity despite the fact that they were victims of the German invasion. Thus the Obourg Artificial Silk Co. reports a profit of 2,142,757 francs for four months' operation in 1919. Work was resumed after ten months' work of restoration, only half the company's installation having been put into service. The other part has been restored and will be in operation soon if supplies of raw material are not lacking. The war damage to the company's property is estimated at 2,500,000 francs, 1914 value.

FIG. 1. A. S. & R. CO.'S EXPERIMENTAL FARM

Showing experimental plots of large numbers of common crops for determining effects of SO_2 under varying conditions of light, temperature, relative humidity and stage of growth. During seasons of 1915, 1916 and 1917 more than 3,500 plots were used. Each plot contains 25 sq.ft. and the space allowed for each plant of the various crops is such as should obtain under normal field conditions as determined by good farm practice.

Smoke Litigation in Salt Lake Valley

Notes on the Effects of Smoke Suits and Recent Crop Investigations on Smelting Operations in That Vicinity, the Improvements Made at Murray to Mitigate Nuisances, and the Court's Remarks on the Difficulty of Distinguishing SO_2 Injury

By ERNEST E. THUM

ANOTHER chapter in the smoke litigation involving smelters operating in the Salt Lake Valley, Utah, was brought to a close on Feb. 21, 1920, when Federal Judge T. D. Johnson signed an interlocutory decree permitting, under certain conditions, the continuance of operation of the American Smelting & Refining Co.'s works at Murray and the United States Smelting Co.'s works at Midvale.

In order properly to appreciate the condition surrounding this decree, it is well to turn back fourteen years or more. At that time Salt Lake City was spoken of as the largest smelting center in the United States, with no less than seven different plants, having a combined capacity in lead and copper ores of 8,000 tons of lead and copper ores daily. These seven were doing the work which a long line of foregoing operators had conducted thereabouts in small smelters since the beginnings of mining in Utah. An enumeration of the plants operating in 1906 follows:

Name of Plant	Kind of Smelter	Capacity, Daily Tons
Murray, A. S. & R. Co.	Lead	1,500
Garfield, A. S. & R. Co.	Copper	1,250
Bingham	Copper	1,000
Midvale, U. S. S. R. & M. Co.	Copper and lead	2,500
Yampa	Copper	500
Highland Boy	Copper	1,000
Utah Consolidated	Copper	250

Before 1906, however, all of these plants, without exception, were operating with little or no regard for the recovery of fume and dust. None of them except the newly built Garfield smelter had an organized flue and stack system; each relied upon small individual chimneys located close to each furnace or department.

In the light of our present information about smoke and fume it is not surprising that under such circumstances quite severe damage was done throughout a considerable area surrounding each of the smelters. Consequently, upon suit of 409 farmers, Federal Judge John A. Marshall, on Nov. 5, 1906, enjoined certain of these smelters from continuing the smelting of ores containing more than 10 per cent of sulphur, except after installing satisfactory means for neutralizing the obnoxious fumes resulting therefrom. Pending an appeal on this suit, the smelters continued operating.

However, the Murray plant of the American Smelting & Refining Co. immediately erected a large baghouse (first operated in July, 1907) for eliminating solid particles from the gas. This was in line with the contention made by some of the smelting companies that the damage was largely due to compounds of sulphur and arsenic which condensed on particles of soot or other solid matter and settled with them to the ground. Naturally, then, if soot and solidified vapors could be filtered out of the smoke, little cause for damage would remain. After making the proper financial settlements with the complaining farmers, the American Smelting & Refining Co. was, therefore, freed from the litigation and was allowed to operate nine or ten lead blast furnaces. In its operations it was also allowed to roast ores containing 25 per cent of sulphur and to smelt ores containing more than 10 per cent, if the average of the furnace charge was no more than 10 per cent sulphur and if, in addition, all furnace gases were baghoused, removing lead, arsenic and other solids. The company also agreed to construct an extensive dust chamber at the roaster department to cool the gases from those operations so as to precipitate all the condensable vapors possible.

The same company's plant at Garfield was situated between the Great Salt Lake and Oquirrh Mountains in such a way that the smoke was not carried over farming lands by the prevailing winds. However, in

order to be doubly safe, the company purchased about 35,000 acres of ground along the lake shore to insure against future smoke litigation by the owners.

The United States Smelting Co., however, was not so successful in its negotiations with the farmers and when, on Jan. 11, 1908, the Federal court's injunction was sustained under appeal, its plant closed. Within a couple of months, however, the company petitioned the court for the right to reopen, claiming that its newly perfected Sprague process of introducing zinc oxide into the smoke would remove all cause for crop injury. At the same time the zinc would neutralize sulphuric acid, forming with it a solid which would be caught by the bags. This would improve the quality of the issuing gases as well as prevent rapid deterioration of the bags themselves. On April 5, therefore, the Federal Judge suspended the injunction and allowed the Midvale plant to operate its lead furnaces, treating 25 per cent sulphur ore up to one-third of its capacity. However, it was stipulated that the plant must also remove all solids from its roaster and blast-furnace gases, discharging all smoke through a single smokestack free of lead, copper, arsenic and antimony compounds and all traces of sulphur trioxide. At the same time its percentage of sulphur dioxide must be no greater than 0.75 per cent. Under such circumstances the plant was allowed to run three years in order to demonstrate the efficiency of baghousing in conjunction with the Sprague process.

As a matter of collateral interest the fate of the other plants in that region is more or less interesting. The Bingham copper smelter was abandoned in December, 1907. For some time there were rumors that a more modern plant would be built and placed upon the south shore of the Great Salt Lake, but these plans did not materialize.

Many Plants Dismantled

On the other hand, there were several meetings between representatives of the farmers and the owners of the Highland Boy plant, in which an agreement was sought. It was reported at the time that the farmers demanded a bonus of $175,000 before they would agree to any modification of the injunction against that smelter, while the company said that $100,000 plus actual damages was its limit. On account of this deadlock, a satisfactory arrangement was made with the International Smelting Co. for ore treatment at a new plant, then under contemplation. The Highland Boy smelter was therefore closed down and dismantled, the best of the machinery being reinstalled by the International company at Tooele. This plant was built at Pine Canyon, where prevailing day winds would carry the smoke into the mountains. Preliminary agreements were made with nearly all the land owners within a three-mile radius that in case smoke damage resulted title to the land would be transferred to the company for a certain stipulated value. The Yampa plant in Bingham Canyon was not involved, being out of the smoke zone. However, its life was relatively short.

Under these circumstances it is seen that the smelters at Murray and at Midvale are the two survivors of the cluster operating in that region in 1906, and disrupted by smoke suits. The so-called Godfrey decree and its subsequent stipulations required the American Smelting & Refining Co. and the United States Smelting Co. to install modern fume-collecting and gas-cleaning devices to efface the evident nuisances existing at that time. Subsequent operation of both of the plants proved satisfactory to the farmers for many years. However, during the period from 1912 to 1916 several complaints were made, and in 1916 another suit was entered against the two smelting companies asking damages and other relief.

Investigating Staffs Maintained

During this time both of the companies have maintained investigating staffs which have not only worked upon the question of smoke injury in general, but have also operated experimental farms nearby the smelters (Fig. 1). It was their practice to have members of their staff investigate complaints as they were made. The American Smelting & Refining Co. in many cases found it best to admit damage by sulphur dioxide and settle accordingly. It is interesting to note that it took some years for both sides to become convinced that fume or other solid was not the *sole* cause of plant injury. However, with the operation of well-designed baghouses, the amount of solid matter escaping from the central stack was of negligible quantity, and yet undoubted discoloration and bleaching of foliage occurred at times. However, the United States Smelting Co. would not admit that SO_2, in the concentrations caused by their operators, caused any economic damage—that is, deteriorated the crops in quantity or quality. Their contention was that only on one occasion—in June, 1914—was there a well-defined burn caused by smoke, yet the effects of this gas current quickly disappeared, and no permanent damage was done to the crops nor claimed by the farmers.

Practical Experiments on Nearby Farm

As mentioned above, the United States Smelting Co. had maintained an investigating staff on smoke problems, as well as utilizing the services of independent experts since 1908. In 1914 is acquired a run-down 180-acre farm, one mile from its stack in the direction of the prevailing wind, a farm which had been worked almost continuously since the Mormon settlement without regard to crop rotation or adequate fertilization. Prof. E. W. Ledyard was given charge of this venture, and by proper care, fertilization and drainage he was able to grow successfully over 100 different crop varieties. His studies of the actual SO_2 concentrations led him to the extreme of making determinations at various stations at five-minute intervals for 100 hours. His studies of drainage conditions and ground water were very minute, and led him to maintain that much if not a great majority of the plant bleaching ascribed to smelter smoke was due to improper irrigation or drainage.

Within the last several years the American Smelting & Refining Co. has acted upon the findings of its smoke investigators, headed by Dr. P. J. O'Gara. These conclusions were briefly described in Metallurgical & Chemical Engineering, vol. 17, p. 682 (Dec. 15, 1917). Dr. O'Gara and certain members of his staff by means of experimentation briefly indicated in the article quoted, and illustrated in Figs. 1 and 2, established the standards of plant injury as determined by weather factors and varying concentration of SO_2, and whenever what appeared to them to be actual SO_2 injury occurred they were ready to recommend proper compensation. The logical consequences of these findings involved the construction of a number of improvements at the Murray plant such as the installation of a 455-ft. stack with flues so arranged that it will discharge the smoke from the boiler houses as well as from the roasting depart-

ments. In case the heat derived from this source is not sufficient to insure proper diffusion of sulphur dioxide, an auxiliary coal furnace has been installed at the base of the stack. In conjunction with this device the company has also completed a very fine and efficient Cottrell plant, designed and constructed by its engineer, J. B. McIntosh.

In the decree just issued Judge Johnson notes that conditions at the present time are much better than they were in 1908, but still there was much to be desired in 1916, when the suit was started. He finds that

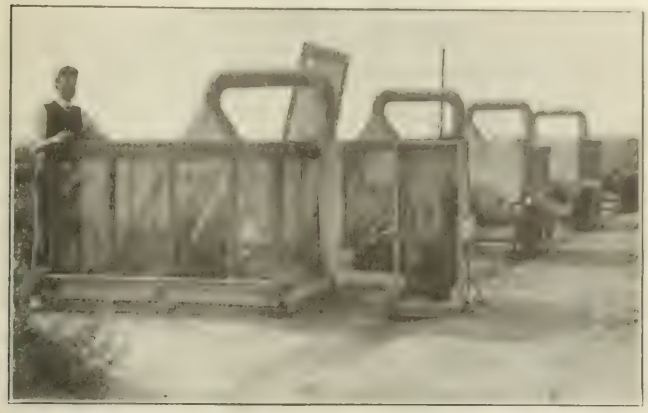

FIG. 2. BATTERY OF CABINETS IN ACTION AT THE A. S. & R. FARM

The cabinets shown are set over the plots when it is desired to fumigate the plants. The light wood frames are covered with thin sheet celluloid, which gives a high light factor. The blower is connected with slip joint to the cabinet delivery pipe, and the volume of air measured by Pitot tube. The SO_2 is measured by a capillary meter shown in the frame above the blower. The temperature and humidity of the air in the cabinets remain essentially the same as the outside air, because of the large volume of air passed through the cabinets. Each blower has a capacity of 10,000,000 c.c. per minute. The cabinets are 6 x 6 x 4 ft. high. In all series of experiments use was made of check cabinets through which air, unmixed with SO_2, was passed. This was for the purpose of checking the light factor.

smoke damage by sulphur dioxide has occurred at many times and many places in Salt Lake Valley in recent years. He also finds that the smelting plants have not at all times been able to control or dilute the sulphur dioxide so as to avoid damage to nearby vegetation. The American Smelting & Refining Co., by its so-called "sea-captain" methods of operation pending completion of the high stack and electrical precipitator, has much more nearly approached perfection—in fact, the Court was able to find no specific case of smoke injury in the Murray zone during the 1916 season. In this system the management recognizes certain optimum conditions of light, temperature, humidity and wind direction, which, when occurring, are bound to cause smoke injury if more than a certain quantity of sulphur is being evolved at that time. By keeping the weather eye out, therefore, the company is enabled to close down certain smelting units (roasters) so as to reduce the actual amount of sulphur evolved during these dangerous times.

Under all of these circumstances the Judge allows operation to continue temporarily, provided that sulphur trioxide or sulphuric acid is neutralized, precipitated or removed to such an extent that "no injurious amount" exists in the gases eventually discharged. All solid products except unconsumed carbon are removed as far as practicable by modern baghouse plants or Cottrell installations, and the resulting fume is resmelted under the same precautions as to smoke and fume which is given the ordinary ore mixture. Sulphur dioxide in the smelter gases at the United States Smelting Co. may not exceed a maximum of 0.75 per cent by volume. On the other hand, the sulphur dioxide analysis on the areas surrounding the American Smelting & Refining Co.'s plant may not exceed an hourly average of one part per million in the growing season of the year, while during the non-growing seasons three parts per million may not be exceeded.

The complaining farmers were awarded $20,000 in costs. The companies are also to bear the expense of a commissioner and his staff appointed by the court to observe smelting operations, to make necessary tests and to propose remedies for smoke nuisances, and to examine complaints, having, together with the smelting companies' agents, full freedom of action and information from both parties to any controversy. Prof. R. E. Swain of Leland Stanford University was appointed commissioner and will make his report to the Judge on Feb. 1, 1921. If Prof. Swain reports and the Court decrees that the methods employed by the American Smelting & Refining Co. will in all probability obviate smoke damage, then the United States Smelting Co. is obligated to take like steps immediately.

Having given the foregoing historical background, some extracts from Judge Johnson's decision will be of interest to those who have been engaged in investigating or fighting smoke damage.

In the case under discussion, the complainants say that sulphur dioxide and sulphur trioxide escape from the smelters and are offensive to the inhabitants, deteriorate wire screens, fencing and metal work, and

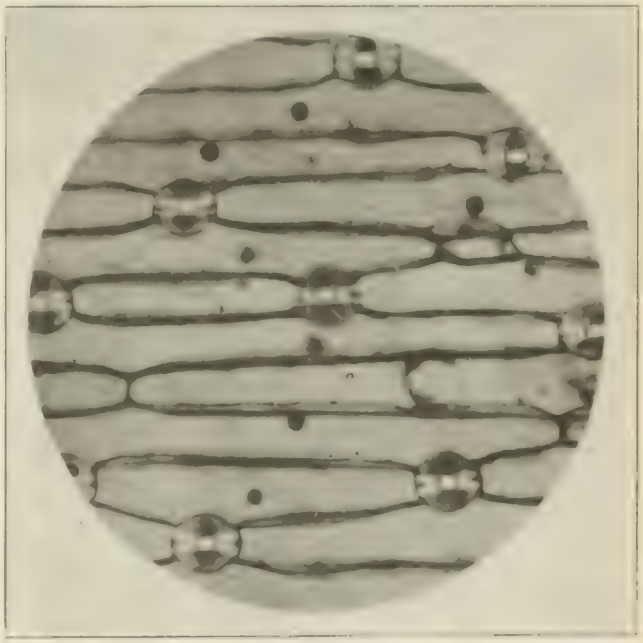

FIG. 3

Stomata or breathing pores of plant leaf, showing open and closed cells. It is through these small openings that gases pass into the leaf. While 100 to 400 stomata may be present on 1 square mm. of leaf surface, there are a few cases where there may be as many as 700. Very young leaves with immature stomata are more resistant to SO_2 and other gases than mature leaves. (Oblique × 175.)

destroy fruit and ornamental trees. Such gases, in connection with arsenic, antimony and zinc compounds, poison crops so that they cannot be used.

On the other hand, the smelting companies contend that no arsenic or sulphur trioxide escapes except when the bags in their baghouses are being shaken, which happens once a day. The amount of noxious fumes

liberated at that time is so small as to be entirely negligible. On the other hand, sulphur dioxide is so diluted by nitrogen and air as to be harmless to animal or vegetable life, and in such quantities is incapable of causing deterioration of metal work.

The Judge finds that practically all sulphur dioxide goes out of the smelters through their main chimneys, except a little "ground gas." In both plants a very efficient smoke-collecting system, flue and baghouse have been installed, which collectively remove all solids from the gas. Sulphur trioxide is sufficiently neutralized by calcium oxide or zinc oxide intentionally introduced into the flues, and thus is converted into solids. Consequently, any damage that is done at the present time is, by exclusion, due to sulphur dioxide.

The evidence shows sharp controversies over the causes of observed plant injury, but a great portion of the evidence was merely a matter of opinion and was of a relative value, being highly influenced by the preconceptions and point of view of the witness. Thus, the plaintiffs and their witnesses were all farmers who were untrained observers and prone to call damage of all sorts "smoke damage," reasoning from conditions which they had observed prior to 1908. They would therefore testify that smoke was responsible even when plant damage was clearly due to other causes. Even the expert witnesses employed by the farmers mistakenly held that leaf injury which looked like sulphur dioxide injury was actually caused by SO_2.

On the other hand, the smelting companies' witnesses were unconsciously biased on the other side—even the farmers who testified for them. The smelting companies' experts often found other sufficient causes than sulphur dioxide to account for all mischief in the smoke zone. However, the testimony of the smelter experts as to fact is far more valuable than other testimony merely founded on opinion.

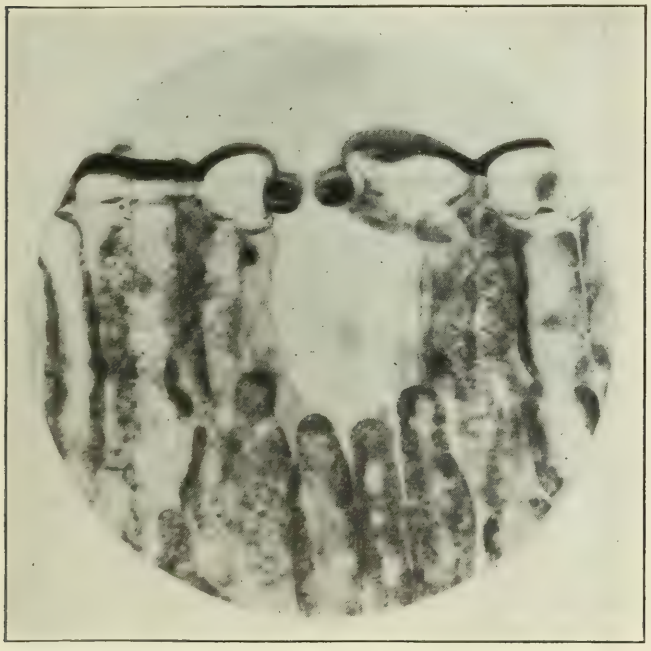

FIG. 4

Cross-section through single stoma or breathing pore of alfalfa leaf. The two guard cells, the sub-stomatic chamber and the palisade cells below and surrounding the chamber are shown. Gases passing through the stoma and into the chamber come into contact with the thin cell walls, and readily diffuse through them into the cells. In this way CO_2 enters the leaf cells and through the agency of light combines with the cell water, sugar being one of the first recognizable products. (O'Gara. × 175.)

The research work of these scientific men has been admirable, and it is unfortunate that the plaintiffs and other farmers of the community have not taken more interest in the experimental farms of the defendants and profited by the information acquired in the operation of said farms and the experiments made at these stations.

Another point in the opinion handed down by the Judge is especially worthy of note and consideration. He says that the experts employed by the American Smelting & Refining Co. have been able to make some settlements with the complaining farmers. Their scientific investigations were of the highest class and their officials were of an open mind. Consequently the settlements which had been made by them tended to establish standards of appearances, circumstances and conditions which evidence injury by sulphur dioxide.

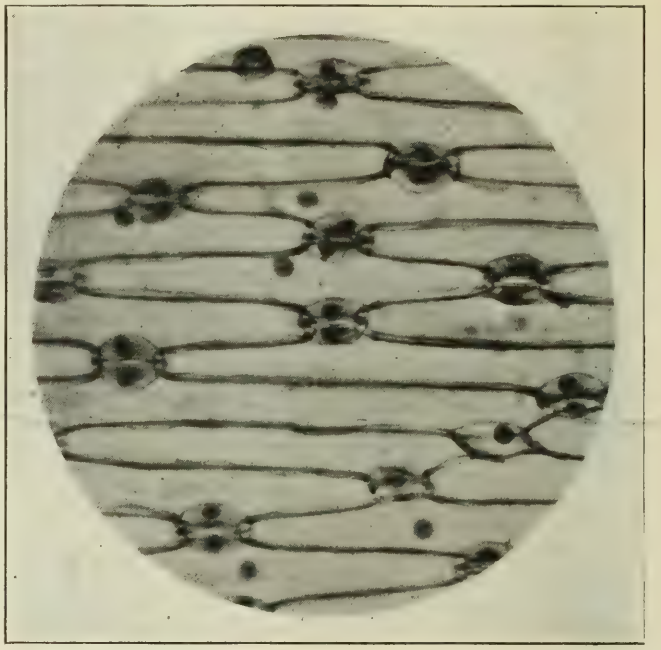

FIG. 5

Stomata or breathing pores of plant leaf, showing closed appearance. In many plants closure takes place in the absence of light, but temperature and relative humidity of the asmosphere are also important factors which govern stomatal movements. The effect of rain drops on foliage is to close the stomata. (O'Gara. × 175.)

Discussing the accepted fact of plant injury by sulphur dioxide, the Judge notes that it is immaterial whether SO_2 is oxidized to SO_3 in the ground, in the air or in the plant tissue itself. The main fact is that under such conditions it actually causes harm to plant life if in sufficient concentration.

He throws out of court, however, analyses showing the sulphur contents of the ground, the plants growing on the ground and momentary quantities in the air. All of these data he feels are too meager for much weight, and sulphur contents in plants might not affect their vitality or their proper use.

> Such a condition evidences a departure from the usual and, perhaps, natural, but the power of adjustment of life to environment is too great to base upon such departure alone the conclusion that it produces a deterioration in the vitality of the plant, or the quality or quantity of yield.
>
> The evidence respecting the effect of the presence of SO_2 or possibly SO_3 in the atmosphere upon wire screening and fencing creates a suspicion that deterioration results, but the evidence is not of that convincing character that I feel would justify a finding in the case to that effect.
>
> The evidence is insufficient to show that the presence

of SO_2 in the atmosphere causes injury to vegetation and plant life, where there is not external evidence of injury appearing in the plant. In other words, the evidence is insufficient to show any invisible injury to vegetation or plant life occasioned by SO_2 acting either through the soil or the atmosphere.

One part of sulphur dioxide to one million parts of air under certain favorable conditions will mark, dry up or bleach foliage of certain non-resistant crops. The skin or bark of growing plants is much more resistant, while young fruit, blossoms, and grain, while it is heading out, are less resistant than the bark, but more resistant than foliage. The effect seems to be that sulphur dioxide passes from the air to the leaf structure through stomata, destroying cell life and drying up the structure in a way which is visibly evident.

Factors Modifying Smoke Damage

"The appearance of SO_2 injury in the foliage of plants and its extent depend upon certain conditions," quoting verbatim the words of Judge Johnson's decision.

"1. The sensitiveness of the plant to SO_2 injury.

"2. The concentration of SO_2 in the atmosphere.

"3. The length of time during which the plant is subjected to SO_2.

"4. The humidity of the atmosphere.

"5. The presence or absence of those conditions which affect or control the opening or closing of the stomata, as light, darkness, heat and cold.

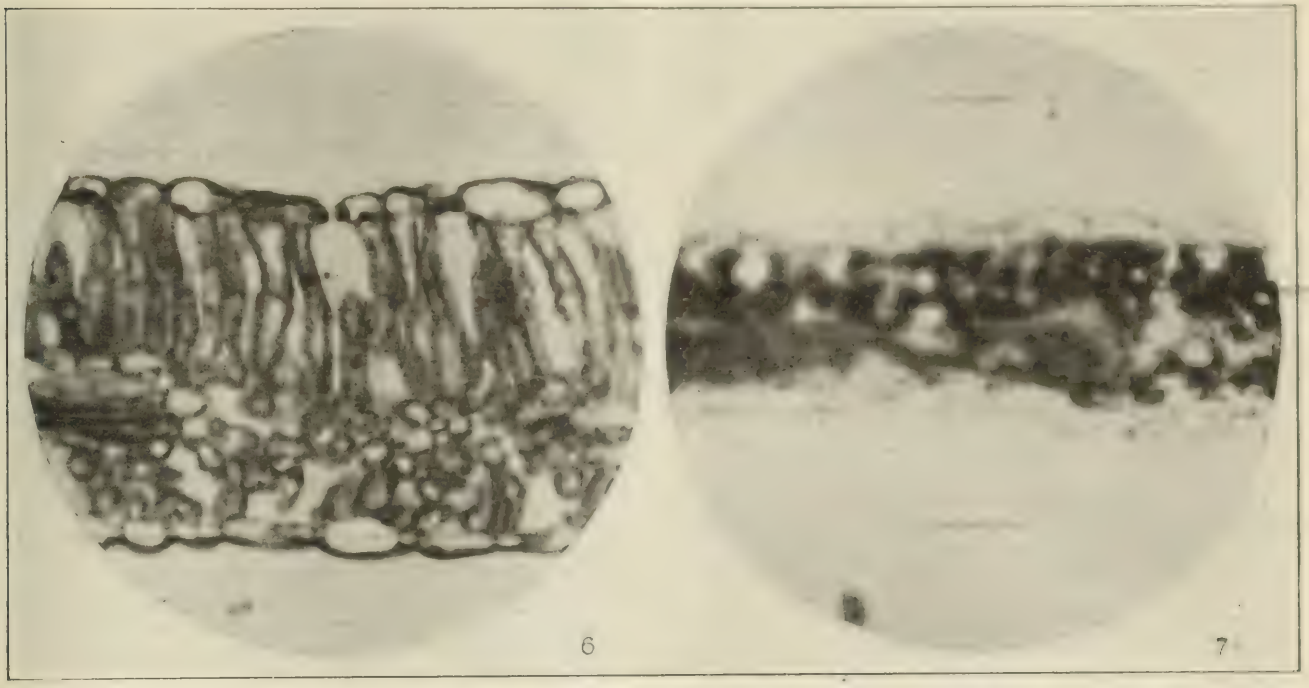
"As a rule SO_2 seems to attack the leaves and foliage at their points and edges, extending into the leaf in proportion to the severity of the injury. The effect of SO_2 injury—that is to say, the markings of the foliage—is observable practically at once. The appearance of the markings of the leaf tends to change somewhat with the lapse of time. The discoloration of the leaves or the appearance of the markings on the leaves resulting from SO_2 injury is not the same in all plants and is not distinguishable from discoloration and markings resulting from many other causes, whether examined by the eye alone or under a microscope, and so far as the evidence discloses there are no structural or chemical characteristics of SO_2 injury which distinguish it from injury by many other causes. Injury caused by frost, sunburn, sun-scald and alkali are among the causes producing leaf injury in every characteristic similar to that caused by SO_2—that is, relatively sudden deterioration, disintegration, and breaking down of the internal cell tissues of the leaf.

"Leaf injury occasioned by insects directly attacking the leaf of the plant is ordinarily readily distinguishable from SO_2 injury. . . .

"Fungous diseases of plants, in many cases, cause leaf deterioration identical with SO_2 injury. These bacterial diseases have each their several characteristics other than leaf deterioration common to them all and to SO_2 injury, and the presence of the characteristics of disease will ordinarily classify the leaf injury as injury resulting from disease and not from the presence of SO_2. . . .

Sulphurous Injury Indistinguishable

"It will be observed that each one of the causes of leaf markings producing injuries identical with and indistinguishable from leaf markings produced by SO_2 has its own peculiar and accompanying factors. For instance, frost is accompanied by a temperature below 32 deg. F., and ordinarily its effect is observed over a relatively large area of country. Sun-scald is accompanied by hot sunshine preceded by irrigation or rain. Sunburn is accompanied by hot weather and lack of



FIGS. 6 AND 7. NORMAL AND INJURED ALFALFA. (O'GARA. × 180.)

Fig. 6 shows cross-section of normal alfalfa leaf with the characteristic cellular appearance or structure. Two stomata, one closed, the other open, are shown in the upper portion of the leaf. The long cells in the upper half are known as palisade cells. Contrast the appearance of the normal structure with that of the injured leaf, Fig. 7, which shows no structure. It is plainly seen that the injured leaf has shrunk to less than one-half its original thickness, as compared with the normal leaf. Fig. 7 shows cross-section of alfalfa leaf after acute SO_2 injury. The cellular structure, as shown in the normal leaf, has practically disappeared. Leaf injury by other gases, fire, frost, drouth and other causes presents the same appearance. There is no distinguishing microscopic picture which will separate one from the other. In all cases the part of the leaf which is injured collapses because the cell water escapes from the injured cells.

moisture. Alkali injury shows on crops in soils containing alkali. Similarly, SO_2 has its accompanying factors—namely, injury from SO_2 always occurs in the path of the wind blowing over and from smelting plant or the stacks from which sulphur dioxide is discharged. . . .

"The lapse of time following an opportunity for injury in any given case is of no aid in distinguishing the cause of the trouble, since under like conditions recovery from the effect of leaf injury caused by sunscald or sunburn, and in some cases alkali, is equally rapid as recovery from injury occasioned by SO_2. . . . It should be noted, however, that in many cases alkali injury persists and is progressive, so that it often happens that a growing crop may show the effect of alkali at first by relatively few and insignificant markings, but these markings, as time elapses, constantly increase in number and extent and persist throughout the growing season.

"The distinguishing factor of SO_2 injury, as already observed, is that it occurs in the path of the wind passing over the smelter. I do not mean to say that it may not occur at times of apparent calm, but in respect to that I think it may be assumed that there is no such thing as absolute calm, or even a practical calm, that extends over any large area for any great length of time. . . .

"Another feature of SO_2 injury distinguishing it from similar markings by other causes is a path or zone of markings showing the course and direction of the gas and which, as above noted, is always in the direction of the wind from the smelter at the time. This path or zone is fan-shaped, increasing in width from the smelter. . . . Yet there are instances shown by evidence of SO_2 injury showing locally and without the accompanying characteristic of a fan-shaped path or zone extending from the smelter, at least observed and traced, and I am led to the conclusion that at times the gas stream is deflected to the ground at points more or less distant from the plant by air currents, with resulting SO_2 injuries. . . .

Economic Loss

"There can be little doubt that SO_2 injury, when occurring at a critical period in plant development, results in economic loss—that is, substantial diminution of crop yield. The tendency of growing crops is to throw off or overcome the injury inflicted by SO_2, or injury caused by any other agent, and the observations of witnesses upon the matter are that markings caused by SO_2 will cease to be noticeable, during the season of rapid growth and development, within a short time, the length of time in any case depending upon the species of the plant affected, the time of year and, generally, upon every factor that promotes or retards plant growth and development.

"The tests made at the experimental farm of the A. S. & R. Co. tend to minimize the economic loss caused by SO_2 injury. There are many factors to be taken into consideration in determining the question of economic loss by SO_2 injury in any particular case.

"Under all the evidence in the case, I am led to the conclusion that SO_2 injury occurring at a critical period in plant developments results in appreciable economic loss. Or, stated another way, SO_2 injury, occurring at a time or under conditions unfavorable to plant development and crop yield, causes more or less economic loss."

Use of Liquid Oxygen as an Explosive

Liquid oxygen as an explosive was first used by the Germans in a coal mine in 1897, following Linde's invention of his liquefying apparatus in 1895. Trials made in the Simplon tunnel are said to have been favorable.

In 1900 Claude of France patented the rectification principle. Linde in 1902 designed his rectification apparatus. Both types of apparatus are extensively employed in liquefying gases. In 1904 Dewar of Great Britain invented the Dewar flask—a container for liquefied gases.

It remained for the war to bring out further developments, and its use was widely extended in Germany during this period. The Allied countries, being able to import nitrates from Chile, did not take up its use, but if the war had continued the United States would probably have been compelled to do so. The use of this explosive commercially will now depend upon its own merits.

Experiments of the Bureau of Mines have shown that a liquid oxygen can be prepared with a blasting strength greater than 40 per cent straight nitroglycerine dynamite. The procedure adopted was to place a No. 6 detonator in the inner cartridge, a cheese-cloth sack containing carbonaceous material. The cartridge is soaked in liquid oxygen ten to fifteen minutes in an improved container devised by the Bureau. The cartridge, frozen stiff, is slipped into a pasteboard container, placed in the hole, a wad of cotton placed on it, a brass tube inserted, and clay tamped around the tube. The hole left by the tube provides an outlet for evaporating oxygen until the shot is fired.

Advantages of this explosive compared with dynamite and black blasting powder are lower cost per ton of material blasted, elimination of dangers in transportation from premature ignition, misfires or unexploded sticks in blast hole, in handling and thawing, or in storage magazines.

Disadvantages are: Liquid oxygen, because of its rapid evaporation, must be used quickly after charging, this limiting the number of shots; the maintenance of a liquefying plant near the mines, and the fact that the explosive cannot be used in gaseous coal mines.

This method offers great possibilities for lessening blasting costs in non-gaseous coal mines, and in metal and mineral mines using a chamber method when only a few shots are fired at one time. The chief cost is that of the oxygen. It is thought that this can be decreased through promised improvements in liquefying machines.

Shipments of Sulphur From Sicily

The export of sulphur from Sicily during 1919 amounted to 147,286 tons, as compared with 231,390 tons in 1918. Of this amount approximately 45 per cent was exported to France, the remainder being shipped to Greece, Turkey, Spain, England and South America. There were no sulphur exports to the United States from Sicily during 1919. The estimated amount of stocks on hand on Dec. 31, 1919, amounted to 136,991 tons.

The production slightly improved in 1919 as compared with the immediately preceding years, but is still far below the pre-war figures. Industrial troubles and fires largely contributed toward curtailing the output last year. The outlook for 1920 is not considered very bright on account of the many industrial, transport and exchange difficulties to be contended with.

Pressure and Temperature Relations for Vapor of Liquids

Derivation of Formulæ Giving the Relations of Vapor Pressures—Boiling Pressure Ratios to the Absolute Temperature—Absolute Boiling Point Ratios From Known Physical Constants—Latent Heat of Evaporation, Molecular Weight and Absolute Boiling Point

By P. B. WILLIAMSON

RECENTLY while working out the design of a cracking process for producing gasoline, it was necessary to have, among several other things, some quantitative idea of the change under different pressures of the boiling points of quite a large number of hydrocarbons—especially of the paraffines. On consulting a number of authorities it was found that very little had been published on the vapor-tension phenomena of those compounds and furthermore that substantially nothing had been done toward determining a general expression involving the pressure on a liquid and the latter's boiling point under that pressure—or, in physicochemical terms, the general relation between the temperature of a liquid and its corresponding vapor tension. A search for information on the subject, including, as it did, correspondence with some of the leading physical chemists and research institutions of America, forcibly brought to mind a statement written by the author several years ago in his physics lecture notes: "No definite law is known (1910) connecting the boiling point of a liquid with the pressure; all we can say in general is that the greater the pressure, the higher the boiling point." It is apparent, however, that if such a law does exist, its application would be extremely valuable: First as a check on experimental work on the vapor-tension variation of liquids; secondly, as a check on the normal boiling point, melting point and density of liquids; and thirdly, for practical determination of the vapor-tension behavior of liquids on which no vapor-tension data have yet been published.

Bertrand's Empirical Formula

In reviewing the literature it was found that Bertrand had investigated twenty-two liquids and found the following equation to be applicable to them:

$$P = G\left(\frac{T_p - \lambda}{T_p - \frac{\lambda}{g}}\right)^g \qquad (1)$$

where

g = 50 for twenty-one of the compounds and 20 for chloroform.

P = pressure in mm. of mercury.

T_p = 274 + pressure boiling point in deg. C.

G, λ = constants peculiar to each liquid.

The use of this formula entails the determination for each liquid of three constants, g, G and λ. In order to simplify the expression the first step made was to modify (1) so as to give the pressure in atmospheres, to do which the following analysis rapidly ensued:

$$P \div p = \text{a constant, } c \qquad (2)$$

where p = pressure in atmospheres, 760 mm.

Then from (1) for p_n = normal pressure, 1 atmosphere

$$c = P_n = G\left(\frac{T_b - \lambda}{T_b - \frac{\lambda}{g}}\right)^g \qquad (3)$$

where T_b = normal b.p. (abs.) of the liquid.

Substituting (3) in (2) and then multiplying through by p gives

$$P = pG\left(\frac{T_b - \lambda}{T_b - \frac{\lambda}{g}}\right)^g \qquad (4)$$

Whence, from equating the identities (1) and (4) and solving for T_p, we get

$$T_p = \frac{\lambda}{1 - \frac{T_b - \frac{\lambda}{g}}{T_b - \lambda}\sqrt[g]{p}} \qquad (5)$$

from which the constant G has thus been eliminated.

Bertrand reckoned from an absolute zero of —274 deg. and obtained the values of λ enumerated in the table given in sec. 5, p. 520, vol. 1, of Castell-Evans' "Physico-Chemical Tables" (Griffin, London, 1902-11). For an absolute zero of —273.1 deg. those values must be modified accordingly.

Vapor Tension Constant Expressions

Having derived equation (5) it was decided to determine whether there exists a definite relation for each compound between its "vapor-tension constant," λ, and certain of its properties, such as melting points, boiling points, densities and molecular weights.

It is hardly necessary to state that considerable disagreement arises in several instances as to the value assigned to the various properties, such as, for example, the melting point of CO_2, the boiling points of H_2S, CH_3Cl, etc., and on various densities. Naturally the densities must be reduced to some standard; which was taken as 273.1 deg. abs.

Omitting quite a lot of detail, it would appear that λ is given by an equation, say, of the form

$$\lambda = \alpha T_b^{\beta} T_m^{\gamma} d^{\delta} (\log W)^{\epsilon} \qquad (6)$$

in which the coefficient α and the exponents β, γ, δ and ϵ are probably universal constants. The most probable values of these constants may be found from a large number of liquids (using the most positive values of their properties) by solving by the method of least squares the following equation:

$$\log \lambda = \log \alpha + \beta \log T_b + \gamma \log T_m + \delta \log d + \epsilon \log \log W \qquad (7)$$

Not having good facilities for the immense amount of calculation the above method involves, nor the opportunity of determining the correct data needed therefor, no attempt has been made to derive the above constants precisely. It will be shown, however, that a general formula for λ can be found involving only the

comparatively well-known constants of the specified liquid—if not of the form just suggested, yet of some other type of algebraic expression.

According to Bertrand, in his equation (1), for chloroform $g = 20$ and $\lambda = 120$. But using equation (5), for chloroform $g = 50$, as with the other liquids investigated by Bertrand, and $\lambda = 61.6$, which agrees with (6) within the limits of error of the data used. Furthermore, approximate calculations on a large number of compounds picked out at random from the vapor-tension tables in Castell-Evans, pp. 451-523 (vol. 1), considering the limits of error established by the agreement of the authorities quoted therein, make it appear that Bertrand's constant $g = 50$ is probably universal.

The constant λ may be experimentally determined for liquids having no published vapor-tension tables. Thus, rearranging (5) and putting $g = 50$, we get

$$\lambda = \frac{T_p T_b (\sqrt[50]{p} - 1)}{T_p \sqrt[50]{p} - T_b} \qquad (8)$$

When the pressure is normal ($p = 1$ atmosphere), then $T_p = T_b$, and those values substituted in (8) give $\lambda = 0 \div 0$ (indeterminate). Neither by rearrangement nor by successive differentiation of the numerator and denominator of the right-hand side of (8) can the indeterminate form be got rid of. That fact can be proved mathematically, but the proof is too long for inclusion here; and, anyhow, it is apparent that any reduction of (8) to normal pressure will give the constant λ in terms of the normal boiling point T_b. That λ does not depend upon T_b alone readily shows from even a casual inspection of the table. However, by finding a number of boiling points for different pressures (other than normal) a mean value of λ follows from (8).

Degree of Precision of Application of λ

Remarking further on positiveness of tables: Probably the most reliable vapor-tension table given in Castell-Evans is that for water, on p. 461 (vol. 1). Substituting pairs of corresponding values from that table in equation (8) shows that the different values of λ thus obtained do not coincide. Thus, for example,

p	T_p	λ
10	453.41	78.41
50	537.67	78.35
170	625.1	78.94

Since the values of λ thus calculated do not vary uniformly with the pressure p (as they should do, were there any theoretical variation), but, rather, "oscillate," it follows that the thermometry of the table is not exact. In the same manner and, it is reasonable to suppose, on the same account the values of λ calculated from the tables for other liquids vary according to the positiveness of the thermometry involved.

Bertrand's value for water of λ, referring to absolute zero as —274 deg., is 78.3. That value referred to an absolute zero of —273.1 deg. becomes 78.112. By striking a mean among the values calculated back from the table for water by (8), we get $\lambda = 78.5$. The same order of difference applies to λ for those of the other liquids checked. It would appear, then, that Bertrand's values need revision. For engineering calculations, however, all of the variations mentioned so far may be overlooked.

In conclusion, referring to equation (19) it follows the following relation should hold:

$$\lambda = 0.0081 W L_b \qquad (19a)$$

More or less empirical methods have been tried above, deriving expressions involving a constant to be found for each liquid either by experiment or by possibly evolving a general equation for the constant itself. As the first determination, for authoritative purposes, would require considerable laboratory work and the second determination might entail no less and probably much more labor for the theoretical chemist, it seemed desirable to approach the subject from another angle, with the rather astonishing results below.

BERTRAND'S λ TABLE

Substance	Formula	λ	T_m	T_b	W	Log W	d
Carbon dioxide	CO_2	35	195	217	44	1.6435	1
Hydrogen sulphide	H_2S	37.1	188	212	34.1	1.5326	0.88
Ammonia	NH_3	46.7	195	235	17	1.2313	0.623
Cyanogen	(CN)	47.3	239	252	26	1.4151	0.88

Differential Relations

Consider the unsaturated vapor of a pure liquid: From the standpoint of differential relations, it seemed possible that a general solution might ensue from the familiar linear equation always coming up when dealing with "single-energy" effects, viz.:

$$\frac{dT}{dp} + X_1 T = X_2 \qquad (9)$$

where X_1 and X_2 may or may not involve p.

The standard solution of (9) is

$$T = e^{-\int X_1 dp} \cdot \left(\int X_2 e^{\int X_1 dp} \cdot dp + C\right) \qquad (10)$$

where e is the Napierian base and C is an integration constant dependent upon the terminal conditions of the problem.

From the nature of the problem the standard solution (10) calls for any of three combinations, viz.; X_1 and X_2 both involve p; X_1 is a constant and X_2 involves p, and X_1 involves p and X_2 is a constant. The simplest choice is the last. Now the curve plotted between absolute temperatures as ordinates and corresponding pressures as abscissæ theoretically is parallel to the axis of abscissæ when the pressure is infinite; *i.e.*, when $p = \infty$ then $dT \div dp = 0$ and $X_1 T = X_2$. But if X_1 involves p in a certain way then $0 = X_2$ when $p = \infty$, or by the third assumption X_2 is constantly zero; which reduces (10) to

$$T = Ce^{-\int f(p) \cdot dp} \qquad (11)$$

Since the temperature of the liquid has only a theoretical value when the vapor pressure of the liquid is zero, consideration of the terminal conditions as those when p is zero takes us rather too much into the abstract. It is more convenient to consider the integration-constant reference conditions as those under the

normal pressure of one atmosphere; thus obtaining from[1]

$$T_p = T_b\, e^{\tau(p^\zeta - 1)} \qquad (12)$$

where

T_p = temperature of the liquid (absolute C.)
T_b = normal boiling point (abs.) of the liquid
T_p = vapor tension of the liquid in atmospheres
τ, ζ = constants peculiar to each liquid.

Upon applying (12) to over 125 liquids for which the writer had to hand vapor-tension tables, it was found that while $\zeta = \frac{1}{9}$ (approx.)[1] for all of those liquids, on the other hand, τ varied from $\tau = 0.567$ for arsenic trioxide to $\tau = 2.17$ for liquid helium, with an average around 0.8.

Solution of the Vapor Tension Constant Tau

The difficulty with indeterminate forms is met with upon attempting to evaluate τ from (12). But, taking another tack (cf., e.g., "The Principles of Physical Chemistry," by E. W. Washburn, 1st ed., 1915, McGraw-Hill, N. Y., Chap. XII., esp. secs. 1, 2, etc.) this obstacle may be avoided by the use of the well-known expression

$$\left(\frac{\delta p}{\delta T}\right)_{p_1, x} = \frac{L_v}{v_0 T} \qquad (13)$$

where

L_v = molal heat of vaporization of the liquid
v_0 = molal volume of the liquid in the vapor state under conditions p_1, x.

For a theoretically perfect vapor (13) is integrated by

$$\ln \frac{p_1}{p_2} = \frac{L_v}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) \qquad (14)$$

in which

ln = natural logarithm
R = the universal gas constant dependent only upon the units employed.

Now if we put $p_1 = p$, $p_2 = 1$ atmosphere, $T_2 = T_b$, and $T_1 = T_p$ in (14), then

$$\ln p = \frac{L_v}{R}\left(\frac{1}{T_b} - \frac{1}{T_p}\right) \qquad (15)$$

But L_v varies with the temperature in the same manner but in different degree for each liquid and, therefore, introduces the necessity for its positive determination accordingly—as a general rule quite a task within itself. But by considering differential increments Δp and ΔT as added, respectively, to the normal pressure and boiling point, it may be written

$$\left.\begin{aligned} p &= 1 + \Delta p = p_\delta \\ T_p &= T_b + \Delta T = T_\delta \\ L_v &= L_{v_b} \end{aligned}\right\} \qquad (16)$$

But

$$L_{v_b} = WL_b \qquad (17)$$

where

L_b = latent heat of vaporization (say, in calories per gram) at the normal boiling point of the liquid.
W = molecular weight of the liquid.

The last assumptions, then, transform (15) into

$$\ln p_\delta = \frac{WL_b}{R}\left(\frac{1}{T_b} - \frac{1}{T_\delta}\right) \qquad (18)$$

which rearranged gives

$$T_\delta = 1 \Big/ \left(\frac{1}{T_b} - \frac{R}{WL_b} \cdot \ln p_\delta\right) \qquad (19)$$

Now from (12)

$$\tau = \frac{\ln (T_p \div T_b)}{p^\zeta - 1} \qquad (20)$$

Substituting (19) in (20) gives

$$\tau = \frac{1}{p^\zeta - 1} \cdot \ln \left(1 - \frac{RT_b}{WL_b} \cdot \ln p_\delta\right) \qquad (21)$$

The smaller the value assigned to Δp, the more accurate is the relation (21) and, at the same time, the closer to an infinitesimal[2] is $\ln p_\delta$. Hence, taking advantage of the expansion

$$\ln(1 - x) = -x - \tfrac{1}{2}x^2 - \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 - \ldots\ldots \qquad (22)$$

the terms beyond the first on the right-hand side may be disregarded and thus enable us to reduce (21) to

$$\tau = R_1 \frac{T_b}{WL_b} \qquad (23)$$

where R_1 involves R and ζ, which are practically the same for all the liquids investigated. Checking (23) against water, mercury, ether, etc. (in fact, against over fifty liquids, and solids and gases in the liquid state), gives the almost exactly general value $R_1 = 17.42$ (slide rule); that is,

$$\tau = 17.42 \frac{T_b}{WL_b} \qquad (24)$$

an expression involving only the comparatively better known constants of a liquid—the normal boiling point, the molecular weight, and the latent heat of vaporization (at normal b.p.) of the liquid.

A General Vapor Tension Temperature Law

The foregoing analysis gives a basis for the statement that: The temperature of a liquid varies with changing vapor tension according to the logarithmic law; the natural logarithm of any particular temperature (absolute) being equal to a known function of the vapor pressure, plus the natural logarithm of the normal boiling point, or, algebraically

$$T_p = \text{illn}\left[17.42 \frac{T_p}{WL_b}(\sqrt[9]{p} - 1) + \ln T_b\right] \qquad (25)$$

or, using common logarithms,

$$T_p = \text{illog}\left[7.56 \frac{T_p}{WL_b}(\sqrt[9]{p} - 1) + \log T_b\right] \qquad (26)$$

By rearranging (26) an expression for vapor pressure (atmos.) is obtained (27)

$$p = \left[1 + 0.1325 \frac{WL_b}{T_b}(\log T_p - \log T_b)\right]^9 \qquad (27)$$

and for latent heat (calories per gram at normal b.p.) in (28)

$$L_b = 0.1325 \frac{W}{T_b}(\log T_p - \log T_b)(\sqrt[9]{p} - 1)^{-1} \qquad (28)$$

Since the pressure on a liquid is equal in magnitude to the vapor tension (pressure) of the liquid when boiling under that pressure, equation (26)—or (25), or

[1] Thus corresponding to the linear equation $\frac{dT}{dp} - \frac{\tau}{9} p^{\frac{8}{9}} T = 0$

[2] of a higher order than $p^\zeta - 1$

(12) with (24)—arrives at an answer to the question often asked in practice:

"What will be the boiling point of so-and-so when the pressure on it is increased or decreased to such-and-such a value above or below normal?"

Cracking-process engineers, among others, will quickly recognize the query. In applying (26) to petroleum, however, Dalton's Law of Partial Pressures must be considered. In fact, the application to any mixture, whether a constant-boiling one or a fractional-distillation one, supplies enough material for another paper on the subject.

Equation (27), inversely, arrives at conclusions regarding pressures—coming up, say, in superheating problems, etc.

Equation (28) might lead to another method for checking the latent heat of vaporization at the normal boiling point. By experimenting upon a substance whose latent heat determination presents especial difficulty by former methods, a table of temperatures and corresponding pressures may be developed (for the sake of obtaining a mean), and therefrom the value of L_b computed by (20).

Going further, if a substance should present itself and its latent heat and a table similar to that just mentioned can be found, then the molecular weight of the substance directly follows from (28) as

$$W = 7.56 T_b L_b (\sqrt[9]{p} - 1)(\log T_p - \log T_b)^{-1} \quad (29)$$

From Berthelot's equation (cf. Washburn, *loc. cit.*, Chap. II, p. 36, etc.)

$$W = DRT_b \left[1 + \frac{9T_c(T_b^2) - (6T_c^2)}{128 p_c T_b^3}\right] \quad (30)$$

where

D = density of vapor at normal b.p.
T_c = critical temperature (abs.)
p_c = critical pressure (in atmospheres)
R = the gas constant (dependent upon density unit employed).

From (30) there may be obtained an equation for T_c, the critical temperature, or for p_c, the critical pressure, which in connection with (26) or (27) gives a check on either of those properties of a substance. The equations are rather involved—yet worse things could be encountered. It is hardly necessary to state that any property sought in one of the above ways should depend only upon data from other sources, and not upon values previously found by (26) or its modifications.

Appended herewith is a table showing, within the limits of error or of agreement of the data consulted, the remarkably close toeing-to-the-mark of enough substances to justify the above theoretical conclusions. For quite a number of substances no latent-heat figures could be found in references at hand; in which cases, for the purpose of comparison, the latent heat was computed by Trouton's Rule, viz.:

$$\frac{WL_b}{T_b} = \tau_1 \text{ (a constant)} \quad (31)$$

where τ_1 is the same for similar liquids. Referring (31) to (24) shows that

$$\tau = 17.42 \div \tau_1 \quad (32)$$

Application of the Relationships

Discussing the general results of the application of the formulæ, it must be said at the outset that they checked much better than had been anticipated. Only three really glaring departures occur—those of formic acid, acetic acid, and acetic anhydride. But it is to be noted that τ approaches 0.75 from the tables for those three; which is following Trouton's assumption. Also, according to Trouton's Rule, if the latent heats of the three variants are correct as given, then the acetates and the formates should also prove exceptional; but those last, as seen, are among the best performers. Only one latent-heat reference each for formic acid and acetic anhydride could be found; but no less than three widely different values (all at the b.p., of course) were in evidence for acetic acid. Until something more definite regarding the latent heats of those discrepant liquids is forthcoming, the writer feels justified in believing that some peculiar difficulty is attached to the determination of that property of theirs.

The latent-heat data on sulphur were also hopeless (as is usual with $S_?$), and that particular instance was dismissed with the "stroke" of using for S_2 the Trouton Number (τ_1) of O_2.

The propionates, butyrates and volerates appear a little irregular, but a reasonable doubt may be cast upon the thermometry of the tables consulted for them, as well as upon the latent heats given.

In numerous instances of iso-compounds τ is checked better by the formula if the latent heat of the corresponding normal compound be substituted therein.

Only in two or three instances did there seem to appear any tendency to stray away from the value $\frac{1}{9}$ for ζ (in which cases the thermometry was clearly equivocal). The value of ζ begins to change, however, near the melting point. For example, $\zeta = \frac{1}{9}$ for water from 50 deg. (cf. K. & L., p. 40) to the critical temperature. Below 50 deg. ζ changes. That was to be expected from the fact that the present analysis assumes an unsaturated vapor.

Some of the rather pleasing results obtained are the apparent agreement of the gases of extremely low boiling point, of niton (radium emanation), and the figures for arsenic trioxide. The last is a subliming substance, and no boiling point has been found for it heretofore. A theoretical boiling point was, therefore, deduced for As_2O_3 by determining τ from simultaneous equations, thus:

$$\tau = \frac{\ln T_p - \ln T'_p}{\sqrt[b]{p} - \sqrt[9]{p'}}. \quad (33)$$

Then, having τ, the theoretical value of T_b is obtainable from (12); proving to be 650.1 deg. abs. or 377 deg. C. Using that value gives the proper agreement, and the check for τ (against $AsCl_3$) is very close, considering. But what to do with carbon dioxide is a question.

The desirability of using the most positive data obtainable should be emphasized, or in the case of having several authorities, of striking a most probable mean (if necessary, drawing an average curve), it being also advisable, when a lone table is in doubt, to plot a curve which will show whether or not the tabulated data give all points on or very nearly on a smooth curve: e.g., plot a curve between x = mm. and $y = t$ from the table cited for m-amidoxylene. In the heading (p. 42) to their vapor-tension tables Kaye and Laby advise caution: "The thermometry is in many cases somewhat dubious."

Some of the earlier investigators performed monumental labors in producing tables and in working out interpolation formulæ; yet more modern workers, notably Ramsay and Young, with advantage of more

refined methods and apparatus and using stricter criteria, have obtained results that in quite a number of instances, especially at extreme pressures and temperatures, differ very appreciably from those of their predecessors. But it is wonderful, indeed, how much, aside from laying foundations, those searchers of the middle nineteenth century accomplished!

No attempt, therefore, has been made to give long-drawn-out accuracy either to the numerical values in the foregoing equations or to the figures in the table, owing, as just explained, to certain doubts about single-source data and to the disagreement, sometimes close, sometimes wide, of the authorities consulted for multiple-source data. The main thing is a desire to point out that here is a case wherein all liquids—whether mercury, sulphur, cadmium, xenon, water, ether, alcohol, normal compounds, iso-compounds, or what not—apparently follow the same law; which, naturally, leads one to believe that similar general laws exist for other property variations (or for the properties themselves) —such as, for example, variation with temperature of latent heat of vaporization, of viscosity, etc.

Calculations With the Williamson Formula

By Wallace Savage

Some months ago Mr. Williamson contributed his modification of Bertrand's empirical vapor pressure formula in editorial correspondence. Publication of it was withheld until the present time because it did not seem to offer sufficient aid to the overburdened-with-computations engineering profession. However, a new formula, as subsequently developed, can readily be worked with by means of a ln-log slide rule or an alignment chart having similar scales together with a special ninth root scale. Such a chart was designed by the writer and is included herewith.

Upon inspection of it, the reader will observe first the three equidistant scale lines X, Y and Z. Z and X are simple 6-in. log scales and Y has a log scale unit one-half as long, the initial points of the units being in line (1.00, 100 and 100). It is mathematically evident[1] that any straight line connecting an X number with a Z number will give the product of the XZ numbers on Y. Thus, 150 connected with 2 intercepts 300 on Y.

In the formula $\tau(P^{\frac{1}{8}} - 1) = \ln T/T_B$, the values of tau, being simple, are assigned directly to the Z scale. Values of the expression $(P^{\frac{1}{8}} - 1)$ are then computed and scaled at any convenient intervals above X on the the three lines 1, (Values of P 1.002 — 1.02 and 0.998 — 0.098 atmospheres); 2, (1.2 — 2.0 and 0.98 — 0.50) and 3, (1.2 — 100 and 0.83 — 0.005). Thus on the third line, 2 atm. and its reciprocal 0.5 are placed at $(2^{\frac{1}{8}} - 1)$ or $(1.08 - 1) = 0.080$, or 80 as expressed in the X scale units. Ln T/T_B are then scaled in a similar manner over Y on the three lines 1, 2 and 3 so as to be equidistant from Z and the corresponding P lines. Thus four separate alignment charts are obtained in a stack having the Z scale in common.

Upon making many calculations on liquids having known vapor pressures, it was found that the formula was very accurate at temperatures above the boiling point. Very large relative errors were found at lower temperatures, making it seem necessary to vary zeta or tau of the original formula. The latter seemed the more logical because tau is inversely proportional to W, the molecular weight of the liquid, which increases with polymerization, and L_B, the latent heat of evaporation, which also increases. The following data on water and benzol may be taken as typical:

WATER $T/T_B = T$ 373

Deg. C.	370	250	200	150	79	40	20	0
T/T_B	1.72	1.40	1.27	1.13	0.92	0.84	785	732
Press. Atm.	207	39.1	15.3	4.85	507	073	023	006
Cal. Tau	0.67	0.67	0.67	0.67	0.67	0.62	0.47	0.43

BENZOL $T/T_B = T$ 353.4

T/T_B	1.49	1.35	1.20	976	0.89	833	776
Press. Atm.	29.3	14.0	5.70	0.72	238	048	033
Cal. Tau	0.89	0.89	0.89	0.65	0.67	0.63	0.57

Thus readings for water on the chart are correct with tau at 0.67 on Z for all points connecting it with the T (1) — P (1), T (2) — P(2) and T(3) — P(3) scales excepting from 0.30 to 0.005 on the lower side of P(3). However, if a point opposite 0.71 and one-third distant to the T(3) scale is taken, it will be found to determine these lower temperature ratios and pressure readings to a fair degree of accuracy.

The reader is cautioned not to get his scales mixed, bearing in mind that he has four separate and distinct alignment charts, the T and P scales of which have reciprocals, which are always to be used together. The X, Y and Z chart is given for use in the simple multiplications and divisions required in calculating millimeters, absoulte boiling fraction temperatures, etc.

The table of constants included here has two tau values, the first as determined empirically from known vapor pressures and the second from the substitution of L_B in the formula for tau. Where molecular dissociation occurs, the values of tau tend to increase greatly. To make the formula and chart 100 per cent reliable, it will be necessary to have empirical tau values throughout the entire range of temperature to be considered.

Problem Solutions

What is the vapor pressure of mercury at 450 deg. C.? The absolute temperature is first found by adding 273, giving 723 deg. for T_p. Upon looking through the constants of the elements in the first column, the absolute boiling point of mercury is found to be 630 deg. and tau 0.80. The ratio of T_p to T_B is then found to be 1.15 by aligning 630 on X with 723 on Y and taking the point of intersection on Z of this line. The pressure is then found by aligning 0.80, the value of tau, on Z with 1.15 on T(3), the point of intersection on P(3) giving the pressure as 4.4 atmospheres. This is readily converted to millimeters of mercury by aligning 760 on X with 4.4 on Z, giving a line that intersects Y at 3340. Upon looking up the determined mercury vapor pressures in Landolt and Börnstein Tabellen, page 376, five values are given as follows:

Regnault	450 deg. C.	3281.4 mm
Hertz		3429
Ramsay & Young		3296.1
Jewett		3450
Young		3395

If it had been desired to know to what temperature mercury would have to be heated to give a pressure of 10 atmospheres, the procedure would be: Align 10 on P(3) with 0.80 on Z and read 1.255 on T (3). Align 630, the T_B of mercury, on X with 1.255 on Z and read 790 on Y. Then 790 minus 273 gives the temperature as 567 deg. C.

In conclusion, it may be well to point out that the three P scales could have been made to read in any pressure units directly. The T scales can be scaled for any given boiling point liquid, thus forming a direct reading graphical chart of vapor pressures.

Copper and Magnetite in Copper Smelter Slags—II

Chemical and Microscopic Examination of a Series of Representative Slags, Showing How Copper Losses Occur, the Relation of Magnetite to Copper Loss, the Behavior of Converter Slags in Reverberatory Furnaces and Suggestions for Reducing Copper Slag Losses*

BY CHARLES G. MAIER AND G. D. VAN ARSDALE

IN THE first part an attempt has been made to point out certain relationships between magnetite in slags and copper loss, which have been summarized in the final part of this article to form the basis of a tentative rational theory to account for the mechanism of such co-ordination. Before proceeding to this matter, however, the generality of the conditions as described above should be proved to be prevalent in the usual matte-smelting process.

In Table III are shown the results of the application of the silver nitrate method to various slags from smelters other than those connected with the Phelps Dodge Corporation. The results are more or less self-explanatory, for on examination of the table it does not seem justifiable to conclude that the amount of dissolved copper is constant for all slags. The amount of pellet copper shows considerable variation, indicating varying degrees of efficiency of settling, but it is to be noted that the average deviation from the mean content of pellet copper, however small in amount, is nevertheless about equal to the variation observed in the content of the dissolved copper.

Despite the impossibility of proving constancy of dissolved copper for all slags examined, there is no doubt that a distinct similarity exists among these figures, and it seems fair to state that for all samples examined there remains the general classification as to form and content presented in our previous work; of the total copper present in reverberatory slag, a part, usually slightly less than 50 per cent and with an average magnitude of 0.15 per cent, consists of prills of sulphide, whereas the remaining copper is apparently in the dissolved form as sulphide and averages 0.20 per cent.

The microscopic similarity of all slags examined is even more striking than the similarity of quantitative results gained by the use of the silver nitrate method for dissolved and pellet copper. The visual uniformity of the major structure of the slags will be apparent from an examination of a few photographs appended in Figs. 31 to 38. The observation of all samples examined confirms the generality of the following statements.

Mattes as examined show identical two-phase structures consisting of iron sulphide constituent and copper sulphide constituent.

Reverberatory and blast-furnace slags show inclusions of copper sulphide globules approaching the constitution of white metal and present in amounts as specified in Table III. Attachment of gas bubbles is found in all slags for at least a portion of these globules and the disappearance of the iron sulphide phase or its separation from the copper sulphide globules is common to all samples examined.

On crystallization no oxide or silicate forms of copper have been recognizable, but there is considerable variation in the crystalline structure of the silicate phase. In all cases of reverberatory slags the formation of magnetite crystals on solidification is common and, so far as observed, universal.

Converter slags have sulphide globules similar to white metal usually constituting the major portion of the total copper content, and magnetite crystals formed during the fused state are observed in all cases.

No chemical relationship between copper content and slag constitution can be discerned. In taking up a comparison of slag samples from various smelters it was thought that the ability to distinguish dissolved and suspended copper in slags should be a valuable tool in discovering any such relationship which might exist, but a critical examination of the specific results obtained, as tabulated in Table IV, shows no adequate explanation for observed behavior.

SUMMARY OF FACTS

In spite of the possibility of some repetition, the following summing up of our experimental evidence may be of interest in connection with the theory which we wish to develop concerning the relationship of magnetite and copper in slags.

It has been found that copper matte-smelter slags contain their copper content in two forms usually about equal in amount, one of which consists of sulphide inclusions mechanically retained by the slag, the other being in an apparently dissolved form (at least not microscopically visible) which certain chemical aspects of the slag seem to fix, as also sulphide. But it has been also universally found that the pellet of mechanically held sulphide seldom retains the form of its original matte source, but instead loses its iron constituents (compare Figs. 36 and 37). This separation is accompanied by signs of chemical reaction, two products of

*Estimated approximate average.

which may be distinguished. The first of these is a gas which must be, if its origin is in matte, sulphur dioxide, and secondarily; in extreme cases of rather unusual occurrence, the appearance of minute globules of metallic copper.

Experiments with the addition of converter slag to reverberatories have shown both chemically and visually through the microscope that there is connection between magnetite (ferric iron) and a portion of the copper loss, i.e., the globule content. The amount of the latter is proportional to the oxidizing strength of the slag usually indicated by the ferric iron and magnetite content.

The dissolved copper content representing the remainder of the copper is unaffected in total amount by the addition of converter slag to reverbertory, and consequently by the slight increase of oxidizing activity. If the dissolved form exists as sulphide, this fact proves that equilibrium is very closely approached.

Theory of Relationship Between Magnetite and Copper Loss in Slags

The facts summarized above lead to the supposition that in considering the process of reverberatory smelting in reference to copper loss, four types of phenomena or fields of action should be considered. These types are indicated graphically in the chart, Fig. 39, and are separated there by dotted lines, although it is not meant that these actions are separable physically or represented by actual spatial zones of the furnace. All of the actions presented probably occur simultaneously to a greater or less degree, but it is not impossible that actual spatial separation in a specially designed furnace might not be theoretically desirable.

The first action in smelting to be considered, from the standpoint of copper loss, is primarily the change of physical state due purely to fusion. The primary formation of matte and slag is essentially and inherently a physical transformation, and any reactions involved are of a metathetical type and do not represent any ultimate change in total slag and matte, nor do they seem to be the source of copper loss. For example, we know that the original roasted calcine fed to the furnace may contain part of its copper content as oxide, but the amount of oxide truly fed to the furnace is not easily determined. A typical sample, as taken for analysis, may contain 10 per cent copper with 3 or 4 per cent acid soluble, but the method of sampling, as compared to the practical handling of calcine where it is conveyed in large quantities directly, and with a minimum cooling, from roaster to reverberatory, does not enable one to state definitely that the hot calcines, as usually fed to the furnace, do contain this amount of oxide. Even if the calcine does contain this amount of oxide copper, however, it does not have effect on the final copper loss, since all the copper not in slag (the copper content of the slag is indicated by our work to be sulphide) is finally found in the matte and the reaction $FeS + Cu_2O = Cu_2S + FeO$ must have occurred if the final condition is to be accounted for. This reaction is obviously the reason for the absence of copper oxide forms in the slag, but does not affect the final copper loss except in so far as it inhibits the formation of oxide forms.

While it is possible that some chemical oxidation does occur during the time in which the change from solid to liquid state is taking place, this action is purely secondary and is not truly an essential part of the matte-smelting process as carried on in the reverberatory. Chemical action, except the roasting mentioned above, is at a minimum in the solid charge. As far as *copper* loss is concerned, chemical reactions are not the source of any loss at this stage of the process, and it it justifiable to assume the first and essential action of smelting in reverberatories to be a purely physical change of state, whose only result on the final copper content is the saturation of the slag phase with sulphides and the entrainment of small amounts of sulphide globules in the slag medium.

Having once attained the molten condition, aside from the purely mechanical separation in whole or part of the matte and slag components, the chemical activity of the charge is enormously increased by the change of state, and a new condition, marked *B* in the chart, prevails in which chemical equilibrium tends to find its level. The matte, more or less protected by the fused silicates, does not have opportunity for direct oxidation to the same degree as the slag. In the latter the ferrous oxides or silicates are oxidized to ferric iron, thus increasing the content of the latter due to its original presence in the charge. By this means the fusion aids in the formation or crystallization of magnetite. It has been shown that the magnetite has great tendency to settle through the slag as soon as crystals of any appreciable size are formed, and inevitably thus comes in contact with the matte constituting the bottom of the fluid portion. Large crystals of magnetite are not visible in the usual reverberatory sample (cf. Figs. 2, 8 and 14)[2] and their absence can be explained only on the basis of this settling action, for the formation of minute crystals on cooling and solidification shows that the slag is saturated with ferric iron. Moreover, since the total effect of the reverberatory furnace as a chemical apparatus is at least some little increase in oxidation, magnetite crystals must be continually forming in the molten slag. Since crystals formed during the molten condi-

[2]See pp. 1102, 1103 and 1104.

tion are not visible in the final sample, (e.g., Figs. 6 and 12 show[3] only crystals formed in solidification), it must be true that these crystals have been disintegrated as rapidly as they were formed. Fortunately magnetite is wet by fused sulphides (Figs. 29 and 30)[4], and its life at the bottom of the slag in contact with matte is short. Pictures shown above such as Figs. 27 and 28 indicate clearly the progressive character of the ferric iron or magnetite reacting to be fluxed through the agency of the sulphides. The slowness of the fusion in the viscous slag medium prevents the instantaneous reduction of the magnetite in reverberatory slags, and thus permits photographs of the actual mechanism by which equilibrium is attained to be taken in solid specimens. This is consistent with the absence of visible magnetite in the more thoroughly mixed blast-furnace slags. Accidental contact between sulphide globules in suspension and magnetite is rare in reverberatory slag, but more possible in the blast furnace.

Upon contact with the body of the matte below the slag, the magnetite reacts, setting free sulphur dioxide. The gas rises and carries with it the sulphide globules which constitute the second portion of copper loss in the slag. This loss is inherent in the reaction of sulphur elimination and the variation of metal loss in slag under otherwise constant conditions of charge and temperature must be due to changes in this reaction, loss by solution being normally constant. This action is the essence of stage *C* (Fig. 39), where chemical equilibrium of magnetite-sulphide oxidation approaches a condition balanced by the physical action of gravity, mixing, etc. *B* and *C* together are a dynamic condition which becomes cyclical for all usual phases of furnace operation.

The last phenomenon, *D*, is the purely mechanical one of settling, and although this may primarily be regarded as a direct and necessary sequence of the change of physical state at *A*, it should, nevertheless, be considered as a separate action because it is so profoundly affected by the intervening and previous chemical and physical equilibria of *B* and *C*. The silicate portion thus acts as a medium for the stabilization of sulphur elimination in which ferric iron formed at its gas contact surface becomes magnetite, settles, reacts with matte to eliminate sulphur as dioxide, and to be itself redissolved and fluxed.

The history of the metal loss in reverberatory slags, as influenced by the four phases of smelting as classified in Fig. 39, should be apparent. The original change of physical state at *A* is the initial cause of two sources of copper loss. The first portion is the direct solubility of a part of the sulphide in the silicate fusion. This part is constant in amount for any normal condition of temperature and composition and is materially unaffected by the subsequent equilibria. As a necessary consequence of the action of melting, entrained sulphide globules are formed. These sulphides should not be normally expected to float in the slag unless affected by some subsequent buoyant effect. As far as density and viscosity are concerned, there is no reason why complete separation of such entrained globules should not be obtained merely through the medium of increasing the time of settling.

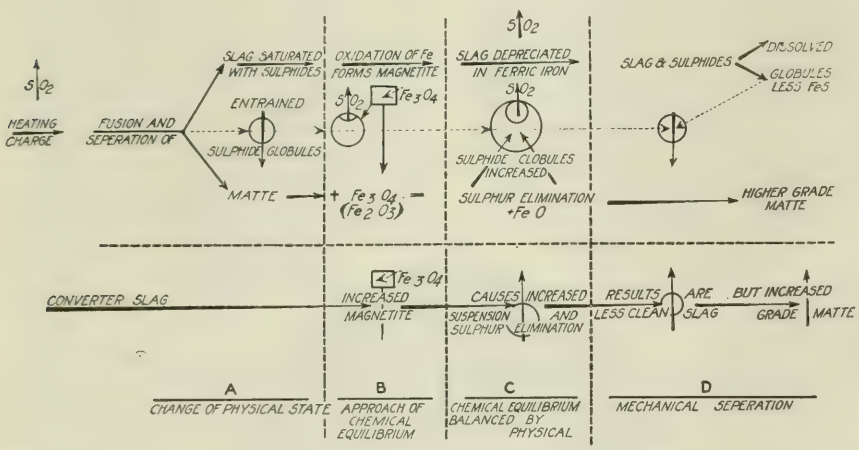

FIG. 39. RELATIONSHIP OF MAGNETITE AND COPPER LOSS IN REVERBERATORY SLAGS

The extent to which contact of magnetite with matte can cause the formation of suspended globules depends obviously upon the rate at which the original magnetite is formed and upon the speed with which it can come in contact with the matte. A limit is reached in state *C*, where the suspension and sulphur elimination are balanced by the physical equilibrium of settling and diffusion, and this represents the final state of the slag as obtained.

The rôle played by converter slag in disturbing slightly the balance of normal conditions, as indicated in the previous paragraph, can now be understood. Its magnetite content increases somewhat the total amount of ferric iron, which is the cause of sulphur elimination in the molten mass, as distinguished from sulphur elimination by roasting action, which is confined to the solid state before fusion. The normal effect of increase in magnetite is an increase in the extent to which sulphur dioxide is produced at the matte surface and consequently results in more suspension of copper globules (sulphide) throughout the slag. At the same time the grade of matte is necessarily increased.

To secure finally the most efficient settling or recovery of sulphides from slag, the modifying effects of iron playing its shuttle game from magnetite crystals to ferrous silicate melts must be considered in its practical aspects.

Certain Practical Aspects of Results

If present and previous work has necessarily been of more theoretical than direct practical application, it has at least indicated rather definitely the answers to some problems which present themselves in considering methods for decreasing the metal loss in copper smelting slags.

In the blast-furnace or reverberatory slags the classification of the losses into two normal classes of dissolved and suspended sulphide globules enables direct prediction of the possible methods for securing decreased loss. Dissolved loss, whether it be due to true or colloidal solution, can only be controlled internally by variation of the temperature or constitution of the melt, or externally by the addition of such reagents as might cause a depression of the solubility by a common constituent (ion?) effect. In a practical way the criteria of satisfactory furnace operation and economy of flux, as well as limitations due to the original constitution of available ores, will tend to render improvement by change of constitution unlikely.

Depression of the solubility by the addition of external agents requires the use of sulphides. Iron is precluded because the slag is already saturated with its sulphide, and further addition could have no effect on the *dissolved* copper portion. Furthermore, the effect of the addition agent would be proportional to the amount added, and consequently no hope of the complete elimination of the dissolved constituent may be entertained, and no practical method whereby a saving of even any considerable amount of the dissolved copper is discernible on this basis.

The elimination of suspended copper globules would seem to have much greater practical possibility, even though the total amount of metal recoverable is limited by the small percentage present in this form. The results outlined above leave no doubt as to the conditions which must prevail to obtain a decrease. Both the initial formation of floating sulphide globules and the continuity of suspension are due to oxidation carried on through the medium of ferric iron and magnetite. Many persons, noting an increase of copper in slag as the grade of matte was increased, have imagined a direct

chemical relationship to exist between the grade of matte and metal loss, but this connection is not truly causative, being in fact a secondary action. Considering the dissolved content, since we know that the constitution of suspended globules approaches that of pure cuprous sulphide, the solubility of copper sulphide in the slag must approach a constant maximum corresponding to equilibrium in accordance with a fixed distribution ratio, one of whose phases approaches a pure material. This means that the grade of matte cannot affect the amount of dissolved copper by any solubility effect. An altogether different condition exists for the globule content. Any process of smelting to give a high-grade matte must necessarily be done under more strongly oxidizing conditions than that producing a low-grade matte, and an increase of suspension is inevitable, because it is just this oxidizing condition which is the source of suspended copper sulphide loss.

In the light of this reasoning, the extent to which the contact of matte and slag is under oxidizing conditions forms the major factor for determining the final copper content of the slag rather than any directly chemical relationship. The necessary conditions under which a saving of suspended copper may be made are clearly a matter of proper non-oxidizing settling, but it must be left to the practical smelter man to design suitable apparatus embodying the above principles for obtaining these conditions in a usable furnace.

Even more definite conclusions are deducible regarding the practical treatment of converter slag. If minimum copper content of slag is desired, the addition of converter slag to normally operated reverberatories is undesirable except under those conditions in which the mixing can be done throughout a zone sufficiently reducing to insure complete reduction of the magnetite. Unless the magnetite is completely fluxed in the presence of excess sulphides, an increased suspension of sulphide globules seems inevitable.

The effect of the addition of converter slag to reverberatories may be practically classified from either of two points of view, regarding the effect on the basis of the per cent saving of copper content of the original converter slag, or with respect to the effect on the original reverberatory slag to which the converter was added. Considering first the saving of copper content of the converter slag, the undesirability of making the addition under any other than completely reducing conditions may be shown by a simple calculation. The original converter slag may normally carry from 3 to 10 per cent of copper, the greater part in the form of suspended globules of white metal with occasionally small amounts of metallic copper. The average dissolved copper content of the converter slag is not nearly so constant as with other slags, but may be assumed to have an average maximum of 0.5 per cent. On addition of the converter slag to the reverberatory, the sulphide globule content of the former might be expected to be amenable to settling and recovery, but it is evident from our work that the recovery of the total globule content is only possible under the strictly reducing conditions mentioned above.

Now assume the normal copper content of reverberatory slags to be 0.40 per cent, of which 0.25 per cent exists as suspended globules and 0.15 per cent as dissolved. Since, as far as microscopic appearance and chemical behavior of the suspended globules in converter slag are concerned, they are exactly similar to those in reverberatory slag, we may assume that the suspension of the original converter globules when present in the mixed slag would certainly not be less than normal but will be greater than normal in proportion to the increase of ferric iron due to the admixture of unfluxed magnetite. A typical case would be represented by the addition of converter slag containing 3 per cent copper, 0.50 per cent of which is dissolved, and with a normal magnetite content of about 25 per cent. If this is now added to the extent of 10 per cent to reverberatory slag with an original 5 per cent magnetite content, the final mixed slag would contain $(5.0 \times 0.9) + (25.0 \times 0.1) = 7.0$ per cent. The suspension of sulphide globules is therefore increased in the ratio

$$(7.0 \div 5.0) \times 0.25 = 0.35 \text{ per cent.}$$

The total amount of the original content of the converter slag which is not recoverable even under the best conditions is therefore the sum of the new suspended copper plus the original dissolved

$$0.50 + 0.35 = 0.85 \text{ per cent} = 28.3 \text{ per cent of total copper.}$$

From the other point of view, with respect to the copper content of the reverberatory slag itself, according to the above calculation, the suspended copper would become 0.35 per cent, giving a total copper content of $0.15 + 0.35 = 0.50$ per cent. This represents an increase of 20 per cent of the total original 0.40 per cent content, whereas the percentage admixture is only 10 per cent. The increased loss due to the addition of the converter slag is greater than the per cent admixture, and the addition must be concluded to be unsatisfactory.

Although the above calculation emphasizes the disadvantages of mixing converter and reverberatory slags so long as reducing conditions do not prevail, it is fortunate that in practice there is always some reducing action at some point in the reverberatory despite the fact that the total effect is one of some oxidation. If it is essential to the routine operations of smelting to add fused converter slag to reverberatories, the practical ideal condition which should be aimed at is obviously to maintain a reducing zone in some part of any given furnace to which admixture is being made.

Better yet will be the results of smelting separately with a pyritic siliceous material, preferably to produce a low-grade matte, in order effectually to reduce the magnetite. Such a process has already been carried out at Anaconda[6].

Finally, the above considerations indicate the possibility that methods of concentration of converter slag other than direct smelting are worth considering, although the practical justification of any method of concentration will be affected by the extent to which the fluxing value of magnetite is usable in smelting by the maintenance of a preponderating reducing atmosphere.

Appendix

The method for the estimation of suspended and dissolved copper in slags by the use of dilute neutral silver nitrate solutions has been given in detail in a previous article and a complete discussion of its justification for this purpose need not be reproduced here. The beautifully definite manner in which it worked in the present instance gives, however, added weight to the consideration of its usefulness as a critical method in the examination of slags.

The determination of ferric iron in slags is a matter

[6] See *Trans.* February, 1920, Meeting of the American Institute of Mining Engineers and CHEM. & MET. ENG., vol. 22, pp. 231 and 317.

of considerable difficulty. Although the total iron is easily determined and an estimation of ferrous iron should complete the solution of the problem, there are two serious difficulties in the way of obtaining accurate results on silicates. These are:

(*a*) The necessity of disintegrating the slag without oxidation.

(*b*) The harmful effects of sulphides in oxidation and reduction reactions involving the state of the iron prevent accurate determinations of ferric iron in their presence.

A number of methods of disintegration have been proposed for determining the ferrous iron in silicates by Hillebrand[6], J. P. Cooke[7] and Doelter[8], based on the use of hydrofluoric and sulphuric acids in an atmosphere of

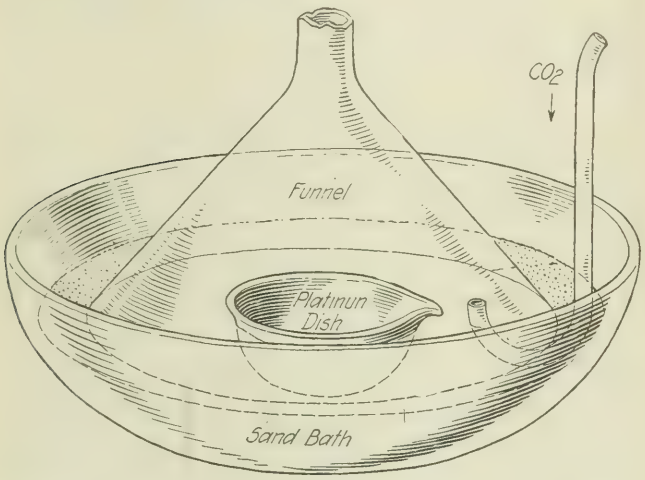

FIG. 40. APPARATUS FOR DISSOLVING SLAG WITHOUT OXIDATION

carbon dioxide. A composite method based on the recommendations of these authorities has been worked out as follows:

From ½ to 1 g. of slag sample ground to 100 mesh in porcelain was weighed out into a 25-c.c. platinum dish, 2 to 3 c.c. concentrated sulphuric acid was added and the whole stirred with a platinum wire. The dish was then immersed in an atmosphere of carbon dioxide over a sand bath, as shown in the illustration Fig. 40. Ten to 12 c.c. of concentrated hydrofluoric acid was added and gentle heat applied for a period of twenty to thirty minutes until, after frequent stirring with a platinum wire through the top of the neckless funnel, complete disintegration had taken place. The heat was then removed and after cooling the contents of the dish were washed into about 300 c.c. of water with warm dilute sulphuric acid.

If one endeavors to titrate for ferrous iron with permanganate in this solution, the presence of hydrofluoric acid remaining undistilled causes a very bad end point because of the reactivity of manganese fluoride toward permanganate. This condition was partially eliminated in the following manner:

Potassium carbonate and pure finely ground quartz in the proportion $4K_2O : SiO_2$ were melted together in a platinum dish to quiet fusion; the silicate thus formed was broken up and dissolved in a minimum of water, and sulphuric acid added until the liquor was quite strongly acid to litmus, thus precipitating gelatinous hydrated silicic acid and forming potassium acid sulphate. An amount of this solution and precipitate corresponding to about 3 g. silica was then added to each determination and the ferrous iron titrated directly with permanganate. Under these circumstances most of the hydrofluoric acid remaining is converted into potassium fluosilicate and the end point is considerably improved.

The determination of ferric iron by this method as the difference between the total and the ferrous iron is perfectly feasible, but the actual amount determined will probably be somewhat less than the true content because of the sulphides present in the slag. For the present work, however, in default of absolute accuracy of results, if the results are comparable they could obviously be made the basis of a theory concerning the relationship of ferric iron to the copper content of slag. The justification of the use of the method depends then on the fact that the total sulphide present in the samples analyzed varies in amount less than a few tenths per cent, whereas several per cent of iron are being determined. Consequently the small practically constant error which is involved, due to the presence of sulphides, has been deemed negligible for present comparative purposes.

Sulphuric Acid Industry in Japan

The following table gives some idea of the sulphuric acid industry in Japan:

	Production lb.	Yen
1912	218,460,500	2,118,960
1913	413,613,100	3,328,950
1914	472,905,000	3,004,220
1915	492,026,600	4,702,660
1916	781,425,520	10,844,860
1917	741,039,160	8,916,830
1918	1,269,200,000	14,250,000

Production for 1914, the year the war broke out, shows an increase of 60,000,000 lb. over the previous year but a decrease in value of 324,730 yen. Since then, however, the production has shown an increase, with a slight let-up in 1917. No exact figures are obtainable for 1919, but it is estimated that the production was not less than 1,300,000,000 lb.

EXPORT TRADE

	Kin	Yen
1914	3,386,760	140,348
1915	13,245,641	501,921
1916	25,008,955	1,517,617
1917	6,949,083	503,594
1918	5,862,000	408,450
1919	5,354,092	436,178

As seen from the above table, there was a considerable increase in the export of sulphuric acid in 1915 and 1916, probably due to increased exports to Russia. Since that time, however, the trade has been diminishing until in 1919 it fell to 5,350,000 kin, valued at 436,000 yen.

The principal countries to which Japan exports sulphuric are China, Dutch India, the Straits Settlements and Hongkong. In 1916, 17,000,000 kin of sulphuric acid valued at 1,000,000 yen was exported to Russia, representing 40 per cent in quantity and 60 per cent in value of the total export, but in 1917 the export to Asiatic Russia fell to 29,000 yen and in 1918 to only 200 yen.

Some quantity of sulphuric acid was exported to Sweden, Siam, the United States and Hawaii in 1915, but the export has ceased since 1916. In 1917, 90,000 yen of acid was exported to Egypt and 80,000 yen in 1918.

Legal Notes

By Wellington Gustin

Armour Fertilizer Works Not in Contempt

Judgment has been reversed, in the contempt case instituted by the State Solicitor General of the Atlanta circuit against the Morris Fertilizer Co., and involving the Armour Fertilizer Works, by the Supreme Court of Georgia. Action in this matter seeking to enjoin and abate the fertilizer works of these companies in Fulton County, Georgia, as a nuisance, was begun in December, 1917. In the court proceedings only the Morris Fertilizer Co. was named as defendant, and a temporary order was obtained restraining it "from permitting any poisonous or noxious gases or vapors to escape from or be carried beyond the ground owned by the defendant company, and upon which its plant is located." This order was subsequently modified, in 1918, to read "The defendant is restrained from permitting any gases or vapors to escape from or be carried beyond the ground owned by the defendant company, and upon which its plant is located, so as to constitute a nuisance, etc."

It appears that Armour Fertilizer Works was never joined as a defendant, but subsequent to the court order an agreement was entered into between the Solicitor General for Atlanta and both defendant Morris Fertilizer Co. and Armour Fertilizer Works in which the Armour Fertilizer Works agreed to abide by the terms of the injunction issued against Morris Fertilizer Co. Upon the application of the Solicitor General and by consent of the Morris company the contract, by order of the court, was made a part of the court record in the case. The Armour Fertilizer Works did not join in this application, and did not consent to the court's order.

Both Companies Cited for Contempt

Later the state filed an application for attachment against both the fertilizer companies for contempt of court by violation of the restraining orders, and the Armour Fertilizer Works was adjudicated a party defendant. Both of the companies demurred to the state's petition and their demurrers were overruled in the trial court, and they took the case, by error, to the Supreme Court of Georgia. Here this court held that the Armour company was not a party to the cause, and was not bound by the judgment of record therein, either (1) by voluntary contract, (2) by order of the court, or (3) by estoppel; and this is true, although the Solicitor General for Atlanta contemplated the filing of a separate suit against the company to enjoin its works as a nuisance.

On the application for attachment for contempt, the court said such a proceeding in which the defendant and one not a party to the case are joined as respondents, and in which acts of the defendant and that person are alleged to constitute, jointly and severally, a contempt, is not good because of misjoinder of parties defendant and misjoinder of causes of action.

Regarding the agreement between the parties, the most that can be said is that though the state contemplated filing a separate petition to abate the Armour factory as a nuisance, the contract was made in settlement of a contemplated suit. A controversy is not a suit, and an agreement with reference thereto, though intended as a final settlement thereof, is merely a contract, and not a judgment of the court. The Armour company could not be held to be a party defendant by estoppel, upon the ground that the making of the contract prevented the filing by the state of a separate suit against it, praying that its factory be enjoined and abated as a nuisance.

The judgment was reversed.

Oral Evidence Inadmissible to Transform Sale by Description Into One by Sample

Some important points of information for the trade have been brought out by the Appellate Division of the Supreme Court of New York in the action of the American Aniline Products, Inc., against Mitsui & Co., Ltd.

Aniline Products brought its action to recover on three contracts for the sale to Mitsui & Co., Ltd., of a quantity of dyes, which the exporter refused to accept or pay for. The latter admitted giving the orders, each of which was alike except as to dates, quantity of dyes and dates of shipment, and that the Aniline company accepted them. It was further admitted that the dyes should be packed in barrels of 400 to 500 lb. net each, instead of 100 lb.

Samples of Dyes Submitted

Mitsui & Co. defends on the ground that prior to the date of the orders, as it alleges, the Aniline company submitted to it a certain sample of dye, and offered to sell to it dyes according to such sample, and represented and agreed and warranted that deliveries of dyes under orders thereafter received from it would be equal in dyeing strength, color, quality and all other respects to the sample submitted; that relying upon this it gave the Aniline company its export orders for the dyes referred to in the complaint. Mitsui & Co. further alleged that when the Aniline company notified it of intention to deliver certain dyestuffs under the orders, an examination was made which showed the dyes did not correspond with the sample; that thereupon the dyes were rejected and Mitsui & Co. refused to accept delivery or pay therefor.

Upon examination of the writing and orders involved, it was found that such contained no reference to a sale by sample, nor did they contain any express warranty as to strength, color or quality. The important proposition in the case, therefore, was whether the exporter could show, by evidence outside the writings sued upon by the Aniline company, that the dyes were warranted to correspond in all respects with a sample.

Evidence of Sale by Sample Ruled Out

While oral statements will not be permitted to change or vary the terms of a written agreement, yet this rule of law does not operate to prevent one from showing a prior, independent and collateral agreement, said the court. Now, while the agreement alleged in the exporter's defense to the suit was a prior one, it is neither independent nor collateral, for it touched upon at least one element in the written order and agreement. That element was the quality of the article sold. The writing shows a sale by description, being "Amacid Blue Black KN," and therefore the obligation of the seller was merely to deliver goods to that description of

merchantable quality, ruled the court. In a sale by sample, the bulk must correspond in quality with the sample. To attempt to transform a sale by description into one by sample is to attempt to vary the obligation of the seller as to the quality of the article to be delivered. This cannot be done, said the court. (89 N. E., 365.) Therefore evidence as to a sale by sample was not permitted in evidence, as it would result in varying a written agreement by parol evidence.

However, the court held that upon the trial either party would be at liberty, by word of mouth, to define the term "Amacid Blue Black KN." The rule of law is that when a term of a written contract requires definition in order to make its meaning clear, and such definition is not found in the writing itself, it is always permissible to give that definition by extrinsic evidence. For such evidence does not vary the meaning of the writing, but, on the contrary, discloses the full meaning of the parties to the instrument.

Regulation Upheld for Computing Drawback Due Exporters

Section 22 of the act of Congress effective Aug. 27, 1894 (28 Stat., 509, 551) provides as follows:

"That where imported materials on which duties have been paid are used in the manufacture of articles manufactured or produced in the United States, there shall be allowed on the exportation of such articles a drawback equal in amount to the duties paid on the materials used, less 1 percentum of such duties . . ."

It is further provided in the section that the drawback due thereon shall be paid to the manufacturer, producer or exporter "under such regulations as the Secretary of the Treasury shall prescribe."

Under this section the National Lead Co. brought suit against the United States to recover the difference between the amount of drawback allowed by the Government to the company, as an exporter of linseed oil cake, and the amount to which it claims to be entitled.

The National Lead Co. imported large quantities of linseed upon which it paid a specific duty of 20c. per bushel of 56 lb. This seed, when treated by a simple process, yielded about 20 lb. of linseed oil and about 36 lb. of linseed oil cake to the bushel. The oil was much more valuable than the oil cake, the latter being composed of the solid substance of the seed and a small amount of oil not recovered, which made it valuable as a feed for stock. It is a byproduct and, except for the small amount of oil in it, would be mere waste. The company exported large quantities of oil cake derived from seed which it had imported and made demand for the drawback provided for by the act of Congress.

In rendering its decision on the case the United States Court of Claims found that:

"From Aug. 5, 1861, to the present time the practice of the Treasury Department, where several articles are manufactured from the same imported material, has been to calculate and to pay the drawback by distributing the duty paid on the imported material between such articles in proportion to the value and not in proportion to their weight, as well where the imported material paid a specific as well as where it paid an ad valorem duty. Such calculation and payment had been made under Treasury Department regulations."

The company appealed its case to the Supreme Court of the United States, which has just handed down its decision. The company claimed that the correct construction of the section requires that the drawback should be computed on the basis of the weights of the oil and oil cake derived by the process of manufacture from the seed, instead of on the basis of the values of the two products, as it was computed by the Government. Hence the question presented to the court was whether the department regulation is a valid interpretation of the statute.

The act provides that the drawback allowed shall be "equal in amount to the duties paid on the material used," less 1 percentum. Now, what was the amount of duty paid on the small amount of oil and on the large amount of solid substance, the hull and the fiber, which made up the exported oil cake? Was it substantially two-thirds of the total, determined by weight—on 36 of 56 lb.—or was it about one-fourth of the total as determined by the relative values of the oil and of the oil cake derived from the seed?

Supreme Court Upholds Regulation

The terms of the statute show that the contingency of having one kind of dutiable material, from which two or more kinds of manufactured products might be derived, is not specifically provided for. The statute, thus indefinite if not ambiguous, called for construction by the Treasury Department and the regulation adopted to cover such cases as here presented was commended and upheld by the Supreme Court.

It says that Congress did not intend that two-thirds of the duty should be returned when one-quarter in value of the manufactured product should be exported; or that the exporter should retain 20 lb. of oil, estimated to be worth about 7½c. a lb., derived from each bushel of seed, and recover two-thirds of the duty paid when he exported 36 lb. of seed cake, worth slightly more than 1c. a lb., derived from the same bushel of seed. But such results would follow if the contentions of the exporter were upheld.

This case is important in that it attacks a regulation of the Treasury Department which has had an extensive and long-continued application to imported and exported material other than such as are here involved.

Seller's Representations Amount to Warranty

The Supreme Court of North Carolina has ordered a new trial in the suit of Swift & Co. against I. M. Meekins and others. The plaintiff sued to recover on a note of defendant given for the purchase of fertilizer. Defendant set up a counter-claim for breach of warranty as to the quality of the fertilizer.

It appears that defendant purchased forty tons of fertilizer, analyzing 5-7-0, and ten tons of acid phosphate. Meekins testified that seller's agent, at the time of sale of the fertilizer, stated that it was as good as any of the same analysis sold to be used for cotton and corn, and was as good fertilizer as there was on the market, and that Swift & Co. would sell it cheaper on account of their output from their packing house. The Supreme Court said these statements amounted to a warranty as a matter of law. It is not necessary that the language should be intentionally false or that there should have been any purpose to deceive. The positive representation by a seller that the article sold possesses a certain value and certain qualities amounts to a warranty, and the purchaser may set up the breach of warranty and reduce the sum claimed by the difference between the contract price and the actual value, although there was no deceit in the sale.

Scientific Control of the Filter Station—IV

A Discussion of Methods Used in Discharging Filter Cake From Presses—Points on Handling Difficultly Discharged Materials—Reverse Current Discharge—Use of Air, Steam, Water and Scrapers—Filtrate and Cake Capacity Ratings—The Economy Curve*

By ARTHUR WRIGHT, M.E.

DISCHARGING the cake is in many respects the keynote of efficiency in filter operation. Any type filter that cannot be operated so as to keep the cloths in a free filtering condition for recurring runs is not only inefficient but a makeshift. Let clarification, washing or drying be faulty and discharge satisfactory, the filters can still operate with a certain degree of economy. More filters are operating poorly by reason of incomplete or time-consuming discharge of the cake than for any other reason, and too many of them needlessly so.

The fundamental principle in discharging the cakes from filters using fabric as the medium is that the cake shall cleave away from the cloth. In filter press operation this is indicated by the cakes falling out of the frames as the operators move up the successive frames. In modern type filters it is demonstrated when the reverse current of a discharging agent—compressed air, steam, water, etc.—disengages the cakes from the cloths and allows the solids to fall by gravity or to be removed by a scraper. In sluicing discharge machines the principle is again proved when the water jet is able to sweep the entire cake away from the cloth.

Difficultly Discharged Materials

When handling materials that cannot be effectively discharged, those filters in which the cloth can be most easily removed and replaced by clean cloths are the best the market affords. Fortunately many materials hitherto resisting all methods of effective discharge are today, by reason of our better knowledge of the art, satisfactorily handled. There can be no refutation to the fact that inefficient operation of filters paves the way for substitute methods of clarification—decantation, flotation, centrifugating, etc.—and faulty discharging discredits filter operation most severely.

As was pointed out in the first article of this series, dense filter cloths are not good mediums for best filter operation. We have come to realize that the filter cloth is best designed when used as an auxiliary filter medium, so that we need no longer choose a filter cloth solely for its clarification properties. This fact alone is responsible for a considerable advance in the better discharge from many installations. No explanation is necessary as to the reason for this. It is apparent that dense cloths retain particles caught in its pores much more than thin or open weave cloths.

Open cloths have a further advantage in that they allow the reverse current of the discharging agent to exert a greater force in disengaging the cake from the filter medium than do dense cloths. The latter balloon out with the introduction of the discharging agent and prevent discharge of the solids—in fact, support the cakes and allow but little of the reverse air or steam to act upon the cakes.

The effectiveness of the discharge is often inaccurately indicated by an observation of the surface of the cloth. The rate of flow on the next cycle is the best proof of the thoroughness of the cleaning action. Some operators working on a granular material see the cake fall from the filter cloth the moment the pressure is released and see no need of further cleaning the cloths by reverse currents. To see those filters hung up while the leaves are taken out and hand scrubbed proves the utter inadequacy of the discharge. To leave only a minute film upon the cloth will in time necessitate strenuous methods in order to regain the original porosity. Thorough discharge is required at all times.

Reverse Current Discharge

Some of the most marked advances in filtration are due to the introduction of those continuous filters which employ reverse current discharge. Filters working on sodium carbonate, free-filtering calcium carbonate or gypsum may not require this means of discharge by reason of their extremely granular or free-filtering characteristics, but cement slurries, kaolin and other finely divided materials are inapplicable without this means of discharge. If some of this kind of material is left on the cloth, recurring filtration causes fine particles to wedge into the deposit and a scale-like, impenetrable mass results and most effectively blocks off further filtration.

The advantage in the use of compressed air, steam or water as the discharging agent is dependent upon local conditions. In leaf filters reverse current through the leaves while they are submerged is often more efficacious than the same current through the leaves suspended in the atmosphere. There is a good reason for this, for with the submerged leaves the water has an opportunity of getting underneath the cake and helps release the cake when the air current issues through the cloth.

Some operators are quick to condemn reverse current discharge because it will in some cases clear small areas on the leaves and leave the remainder undischarged. It is true that if the air can escape through a part of the cake it will not issue through the rest of the leaf forcibly enough to release the cake. Such conditions indicate, however, that either too dense a cloth is being used or else that there is some tenacious constituent in the cake which defies discharge. In this respect it is well to point out the analogy between the nap on the surface of a cotton or cellulose filter cloth and the hair used in plaster for wall and ceilings. Each has a binding action and the nap of the filter cloth is a big factor in causing ineffective discharge, so that metallic fabrics are often advantageous just for this point alone.

It cannot be too strongly emphasized that automatic

*For Parts I, II and III, see CHEM. & MET. ENG., vol. 22, Nos. 22, 23 and 24, June 2, 9 and 16, 1920, pp. 1015, 1077 and 1119.

discharge from leaf type filters is due to the combination of the releasing the cake from the cloth and the fall of the material due to gravity. Therefore any impediment that blocks either factor jeopardizes the discharge. Some cakes have a relatively high tensile strength—are leathery in texture—so that the mere bridging over of the cake at the top of the leaves is sufficient to hold those cakes from discharging. In such cases it is good practice to coat over or cover the rim of the leaves and prevent filtration at this point so that no bridging effect is possible. The same is true of any obstruction which tends to hold the cake, such as bulky side aligning lugs in Sweetland filters, unflattened drainage pipes in leaf construction, etc. If, therefore, the reverse current of compressed air is ineffective in releasing the cake from the surface of the cloth, if the cake is of too small a bulk, or is prevented from falling by some obstruction, the discharge will be unsatisfactory.

Use of Air, Steam, Water or Scraper

Determining whether to use compressed air, steam or water, etc., as the agent for discharge, is a matter best decided in light of local conditions. Generally speaking, however, compressed air is the best. Its pressure is easily controlled, it adds no moisture to the discharge cake and its temperature has no deleterious effects on the filter cloth. It does, of course, have a cooling action and when handling hot liquor it may then be that steam can be substituted to better advantage. Steam has its good points, especially in that the cake, always being cooler than the steam, causes a slight condensation at the inner surface of the cake which often lubricates the surface of the filter cloth and facilitates discharge. Water or any liquid is in a sense the best reverse current because it more forcibly pushes the cake from the cloth, but its use is obviously limited. Unless the leaves are submerged, the water will often fail to remove the upper parts of the cake before it issues through the cloth at the bottom of the leaves and never issue through the upper areas.

When the cakes are thin and have not sufficient bulk to fall of their own weight, when released by the compressed air, discharge from leaf filters is impractical without submerging the leaves or without using scraping methods. If the latter must be resorted to, it must be realized that the scraper has the tendency to smear the cake into the pores of the cloth unless the reverse current of air is operating at the same time. This is the basic reason for the efficiency of discharge in continuous vacuum filters and in the automatic discharge plate and frame presses.

Thickness of Cake

Often thin cakes are held to be incapable of discharge by reverse current methods, whereas the trouble lies in the construction of the filter leaves. When the reverse current of compressed air is first turned into the leaves, the effect is to balloon out the filter bags, especially with dense cloths. When the bag is distended, the upper part of the bag supports the cakes from falling, even though the reverse air has efficiently disengaged the cake from the cloth. This is, obviously, a contrary condition for the best discharge of the cake. It is minimized by securing the cloth to the leaves at intervals across the entire area of each leaf or by lateral stitching of the cloths forming pockets into which wooden slat, etc., drainage members are inserted. Then the ballooning effect is decreased sufficiently that the discharge of the cake is just as efficient at the top of the leaf as at the bottom. In continuous vacuum filters the sections are narrow enough and the wire winding is spaced close enough that ballooning of the cloth gives no trouble with these machines.

Very thin cakes are difficult to discharge, but do not offer the difficulties encountered in discharging cakes that are too thick. In leaf filtration cakes are too thick only when adjacent cakes touch each other. Such a condition is diametrically opposite to the theory of operation in this type of filter. It is fundamental that a space remain between adjacent cakes that there may be room for the free fall of the cakes when released from the filter medium. When the entire space between leaves is filled with cake, it is rarely that the cakes can be discharged. Overcharging of a leaf filter is bad operation and indicative of poor control. If it were that the extra time required for discharge were its only disadvantage it would not be so necessary to emphasize this point. But overcharging is productive of warped leaves and they kill any hope of efficient filtration.

Filtrate and Cake Rating

Overcharging is due either to too long a filtering cycle or to too narrow spacing of the filter leaves. Either condition is easily controlled and good filter operation demands the prompt eradication of those conditions. There are liquors which as the precipitate is commonly formed contain too high a percentage of free-filtering material to be easily controlled in leaf type filters. Wherever possible, these materials should be handled in continuous type filters, which are more adaptable to this class of work, but where temperature, acid content, etc., call for leaf filters, the widest practical spacing should be employed, and if the solids still build too freely, then the liquid content of the material should be increased by returning some of the filtrate.

Consideration of overcharging brings out the point too often overlooked, namely, that the rating or duty of a filter can be either in terms of filtrate delivered or in cake built up. With very free-filtering materials the latter view is the safer, and while it must be measured by the quantity of filtrate delivered or by the time of filtering, it is the prime consideration, for seldom is the economical limit of filtration for such materials reached by waiting for the filtrate to decrease in flow to its economical limit. To do so would build up a cake too voluminous and heavy for the best operation both as regards washing and discharging. In design Sweetland type filters are admirably adapted for those solids which easily fall from the leaves, for the lower half of the machine opens away from the leaves which do not have to move the cakes. In practice, however, the cake in the lower half is often a load in excess of the power of the operating cylinder and makes for dangerous banging of the counter-weights against the shell. Also, the cake remaining in the lower half has to be removed by hoeing it out by hand or hosing it out with water.

When filters are working on liquors containing a small percentage of solids they are better known as clarifiers. In this class of work the solids build up to form only a thin coating on the cloth and a discharge by reverse current methods in leaf filters or any discharge in continuous filters is impracticable. The customary method is to sluice the solids off the filter cloth by forcibly spraying water on the surface of the cloth. This is

efficient when the solids have not penetrated the pores of the cloth. Success of such methods is evidenced by the record of the Merrill plate and frame presses in the cyanide industry and Sweetland filters in cane sugar refineries. In both of these filters the sluicing is done by rocking the sluicing pipe or manifold back and forth so as to project the sluicing streams over the entire surface of the cloth. This operation is invariably done without opening the filter and in respect to cleanliness of operation is distinctly advantageous.

Pre-Coating Aids Discharge

With most materials that are handled in clarifiers and which tend to clog the pores of the filter medium it is indispensable to build up an auxiliary filter medium upon the cloth before commencing the clarifying operation. This medium has been described in the article on Clarification as a "pre-coat," and inasmuch as the pre-coat is easily sluiced from the cloth its advantages are obvious. In sluicing discharge there are two points which must not be overlooked. The sluicing streams must be directed to the cloth with sufficient force to remove the solids and the water must not be allowed to collect in the filter so as to submerge a part of the leaves. Both points should be covered in the design of the machine, but where an ordinary filter is being used as a clarifier the nozzles must be spaced and aligned correctly with the limits of the lateral travel fixed. The drainage at the bottom should be unrestricted and if necessary two drainage openings should be used.

The discharge from gravity tank filters has usually been by the laborious methods of hand shoveling. It is simple, however, to rig up automatic means, especially if wet discharge is not objectionable. All that is required is a drainage opening and to forcibly eject the cake with a water hose. It is also possible to discharge the solids mechanically by using a rotating raking device that can be lifted free of the liquor level while filtration and washing take place and that can be lowered into the cake when ready for discharging. The weight of the rakes will be fed sufficient to plow into the solids. The rakes must, of course, be designed to move the mud toward the outlet provided in the tank.

COMPUTATIONS

Tare:
- 5 minutes filling.
- 5 minutes draining excess and filling with wash water
- 20 minutes washing.
- 2 minutes draining excess water.
- 3 minutes drying.
- 10 minutes discharging.

45 minutes.

Points on curve:
- 45 minutes tare.
- 5 minutes filtering.

50 minutes cycle; 25 gal. flow divided by 50 minutes equals 0.5 gal. per minute.
- 45 minutes tare.
- 40 minutes filtering.

85 minutes cycle: 114.75 gallons flow divided by 85 minutes equals 1.35 gallons per minute.

The Economy Curve

One of the most illuminating graphs arising from modern filtration developments is that known as the economy curve. Engineers will be struck with the similarity of this with that of the conventional "characteristic" curve of centrifugal pumps. The point of flexure is in both cases the economical limit. In the filtration curve it marks the limit of economical filtering cycle more positively than any other curve. While in practice the amount of liquor handled per shift may be said to be an infallible proof of the best working of the filters, the experimenter has this means of predicting that cycle productive of maximum capacity and it is more for his benefit that the curve is insisted upon in good laboratories.

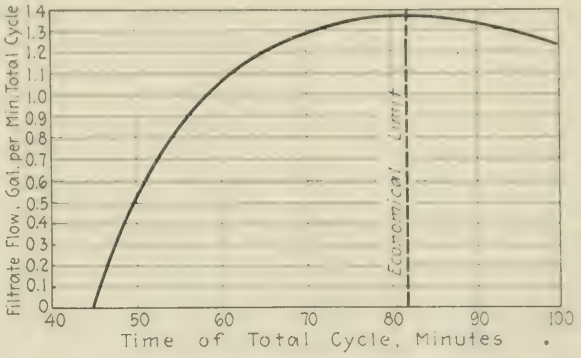

FIG. 7. ECONOMY CURVE

The points on the curve are computations of the rate of flow per minute for each cycle when it is assumed that the tare of the cycle remains constant and that each successive point on the curve is the flow for the cycle if the filtering cycle had ended at that period. The assumption that the tare is constant is based on the fact that the time of filling the filter preparatory to filtering the liquor is a constant, that the time of withdrawing the excess unfiltered liquor and admitting the wash water is almost constant irrespective of the amount of cake deposited, that the withdrawal of the excess wash water takes practically the same time for varying filtering cycles and that the drying, discharging operations and closing up the filter again are practically constants. The time of washing the cakes is a variable with widely differing amounts of cake deposited, but in practice the variation in the length of the washing period is small and for the purpose of this curve can be taken as a constant.

Table I is the form in which it is found most convenient to record the date of a test and from it is computed the points outlining the accompanying curve.

(Part V, General Discussion and Auxiliaries, will be published in a subsequent issue.)

The Potentiometer in Pyrometry

By Charles P. Frey*

DR. GEORGE SIMON OHM published what was originally called "a remarkable mathematical theory" in 1827, and aroused a storm of discussion. It was not until about 1841, when the Copley Medal was awarded to him by the Royal Society of England, that his "theory" was accepted as an axiom, and the importance of his contribution to science fully recognized. Ever since, physicists have labored to establish fundamental units of resistance, current and voltage, and to secure their general adoption.

Fundamental Units

Necessarily, the unit of resistance had to be based upon the physical characteristics of materials; and after much experimenting and discussion the resistance of a column of mercury 106.3 cm. long and 14.4521 g. in mass, having a constant sectional area at 0 deg. C., was adopted and appropriately called the international ohm.

It remains a matter of controversy whether the volt or the ampere can be more easily determined. Since absolute measurements are impossible, the deposition of silver was advocated by many as a medium for current determinations, and the ampere is defined as that current which will deposit 0.001118 g. of silver per second. The electromotive force which will produce such a current, when applied to a conductor having one international ohm resistance, must necessarily be one volt.

The volt, or unit of electromotive force, can now be established with great accuracy by the proper construc-

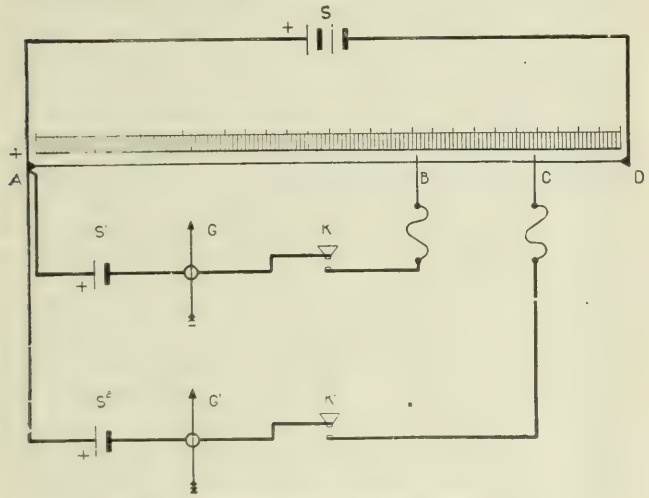

FIG. 1. POTENTIOMETRIC PRINCIPLE

tion of cadmium sulphate cells. The ohm can also be produced in practical form by the substitution of the alloy manganin for mercury.

The Potentiometer

By means of a potentiometer, comparisons of emf. can be made with extraordinary precision. The principle of the potentiometer may be demonstrated as follows, referring to Fig. 1:

A constant current flows from battery S through a resistor $ABCD$, of uniform cross-section. A potential difference is therefore established between the extremes, and between any two points from A to D.

If S^1 is a cell, the known emf. of which is less than that of S, a balance may be obtained when the contactor B connects at a point on the wire found by trial. At that time no current flows through the galvanometer G, with the circuit closed by means of key K. When this is the case, the potential between A and B will be equal to the emf. of the cell S^1. The emf. of the cell S^2 may then be compared with the emf. of S^1 by moving C, and when balanced, $S^2 : S^1 :: AC : AB$, in terms of the emf. of S^1.

The significant feature of this test is the number of unknown values permissible. The current through the

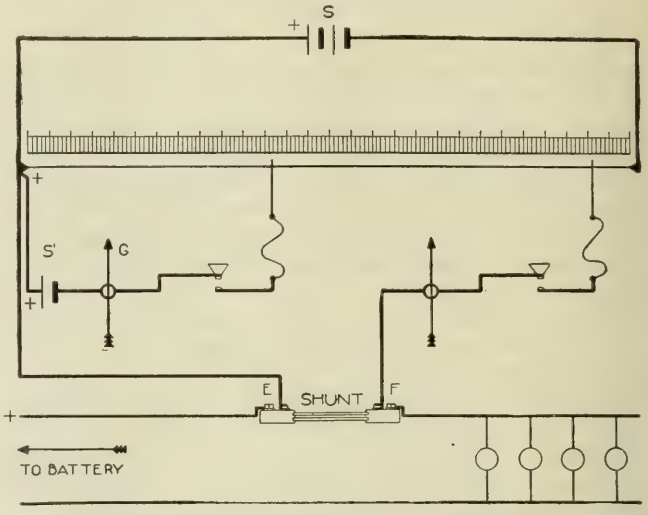

FIG. 2. CURRENT MEASUREMENT BY POTENTIOMETRIC METHOD

feeder circuit including AD, the emf. of S, the resistance of the slide wire and the sensitivity of the galvanometers may all be ignored.

All potentiometers, even the most elaborate and intricate, embody the above principle and depend upon a balance between a known potential and a potential which may be indeterminate. The potentiometer in practical form usually has a calibrated scale which permits direct readings of voltage, or in pyrometry, of temperature equivalents; and by the introduction of proper switches only one galvanometer is required.

In all exact quantitative potentiometer measurements it is necessary that the known emf. has been determined with the utmost exactness and that it is not subject to variations. It is also requisite that the galvanometer is sufficiently sensitive so that when its needle becomes stationary a balance of forces has actually been established.

Current Determinations

The potentiometer may also be used for the measurement of current with great accuracy by the "fall of potential" method or "drop" across the terminals of a shunt.

For instance, if the resistance of the shunt in Fig. 2 is known, the current is determined by finding the drop across EF. This method is necessarily in the nature of laboratory testing and is not direct reading.

By the substitution of a deflecting millivoltmeter in place of the potentiometer, direct indications may be obtained in current measurements, as shown in Fig. 3.

The millivoltmeter scale may be calibrated to indicate amperes, since the current through its movable coil must necessarily be a definite part of the total current undergoing measurement. In this test, the millivoltmeter indications will be a direct index of the drop

*Chief Engineer, the Brown Instrument Co.

across P-P^1, provided the instrument resistance is sufficiently high not to materially reduce the circuit resistance, as a whole, by its own conductivity.

The Movable Coil Galvanometer

Nearly all direct current ammeters, as well as voltmeters, millivoltmeters, galvanometers and pyrometers operating on the movable coil principle, are based on the original investigations of Ampere in 1820.* And it is appropriate to state that all measurements depending upon galvanometers are essentially *current* measurements, although scale readings may be interpreted in volt, ohm, temperature or resistance equivalents.

The degree of accuracy attainable with a deflection galvanometer depends upon the extent of the deflection, also upon the permanence of the magnetic field and the constancy of the controlling forces, such as gravity and the retarding torque of metallic conducting springs or suspension fibers. The temperature coefficients of the conductors are also factors, but errors from such sources can be practically eliminated by the use of properly proportioned materials.

Substitution Checks

In the employment of any measurement apparatus, confidence in the accuracy of its indications is necessary if practical results are desired. Yet if doubt exists, there is always one comparatively easy method by which a check can be made, which is by substitution. Standard weights can be interchanged, thermometers can be read while subjected to the same temperature, two or more millivoltmeters can be connected in multiple, shunts can be checked in series and standard cells can be tested by the opposition method or by replacement.

Potentiometers for Pyrometry

In the selection of a potentiometer best adapted to the requirements of pyrometry, consideration should be given to the fact that since it cannot be adjusted and then read as quickly as the indications of a deflection instrument can be observed, there remains only one reason for its employment, which is on the score of greater accuracy. It also should be designed to be convenient for the measurement of emf.'s which are almost

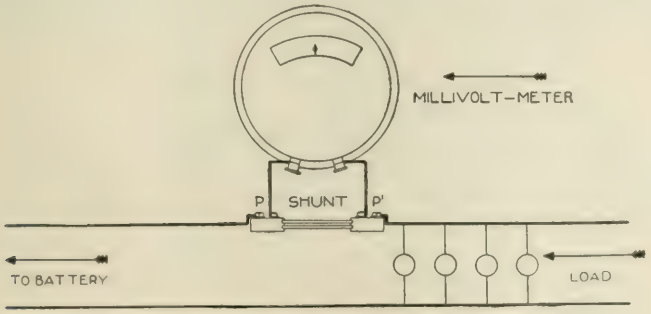

FIG. 3. MILLIVOLTMETER ACTING AS AMMETER

invariably less than 0.05 volt, and have a scale which is not only extremely accurate in its calibration, but which in addition is long enough, or as it is called, sufficiently "open," to permit small differences in potential to be determined with rapidity and precision. If, for instance, such a scale has a length of only about 10 in., and is calibrated to have a range of 0 to 50 millivolts, one millivolt will have a scale length of about 5 mm., or $\frac{1}{5}$ of an inch. Therefore, even if such an instrument is used for measurements near the upper end of the scale and it is possible to read by interpolation to $\frac{1}{10}$ scale division, the extreme limit of accuracy, with no allowance for what is called the personal equation, or error in observation, will be $\frac{1}{2}$ of 1 per cent.

Taking into consideration the fact that a platinum platinum-rhodium standard couple develops only 5.95

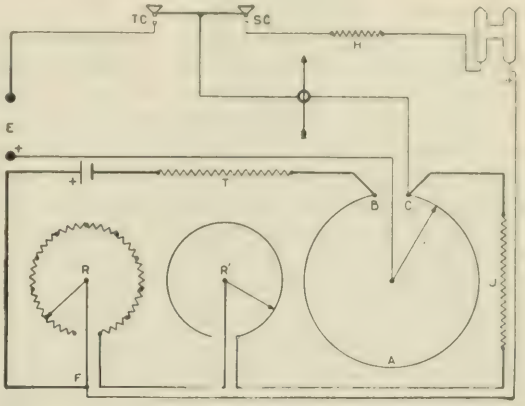

FIG. 4. PORTABLE POTENTIOMETER CIRCUITS

millivolts at a temperature of 1,200 deg. F., it is evident that such an emf. cannot be read with extreme accuracy on a scale which is too short to be sufficiently subdivided.

The scale in the newly developed Brown potentiometer overcomes this objection, since it is 7 ft. 10 in. in length, inscribed spirally upon a drum. The drum wire is wound upon a corresponding insulated cylinder mounted on the same axle and rotating with the scale drum.

The fundamental principle of this instrument may be readily understood by reference to Fig. 4, which illustrates the scheme of an ordinary portable potentiometer. A constant current from the plus side of a small dry cell flows continuously through the rheostats R and R^1, the ballast coil J, the slide wire CAB, and the resistor T, back to the cell. The current through this circuit is regulated by means of the rheostats R and R^1 so that the emf. between C and F will equal the emf. of a selected standard cell. When this is the case the potential drop of the slide wire CAB will have a predetermined value in millivolts between its extremes.

By connecting a source of current at E, its emf. can be determined by balancing it against a suitable part of the emf. of the slide wire. When these cylinders are rotated by means of a knob, an index moves across the scale. The motion of this index is synchronized so that the position of a contactor on the slide wire coincides with a corresponding position of the scale index.

The Standard Cell

Since the accuracy of these potentiometers depends directly upon the emf. of the standard cell, great care has been given to secure satisfactory ones. They conform with the recommendations of the Bureau of Standards and are of the type known as unsaturated.

The Weston normal cell, invented by Edward Weston, containing a saturated solution of cadmium sulphate, was adopted by the Bureau of Standards in 1911 as the standard of emf.; $E = 1.01830$ international volts at 20 deg. C. Saturated cells, if extreme precautions are adopted in their construction, can be produced from different materials and agree within a few parts in 100,000, but owing to the fact that they have a small

*See "The Galvanometer," by E. F. Northrup, CHEM. & MET. ENG., vol. [illegible], p. 941.

temperature coefficient (approximately —0.00004 per deg. C.) they are not preferable for practical measurements, independent of temperature variations.

Another cell, also the invention of Dr. Weston, is identical with the normal standard in ingredients except that the solution used is diluted instead of being saturated. The effect of this dilution is to slightly increase the emf. and to reduce the temperature coefficient to practically zero (—0.00001 per deg. C.). The exact emf. of a properly "aged" cell of this type should lie between 1.0184 and 1.0190 volts, and its voltage will remain constant within 0.01 per cent for years, provided the cell is not short-circuited or otherwise abused.

Since in unsaturated cells the density of the solution affects the emf., this gives manufacturers of precision instruments the advantage of employing cells which are alike in emf. and which may be therefore interchanged. A further advantage lies in the fact that the constant emf. of these cells simplifies the construction of potentiometers, since it obviates the necessity of introducing a thermometer and a device to "set" the instrument to correspond with a definite voltage at a known temperature, which is necessary for precision tests if the usual standard cell is used.

The cell in the Brown potentiometer is packed in a portable case which includes a resistor of about 3,000 ohms, to prevent damage in case of accidental short-circuit. This case can be speedily removed if it is considered desirable to have the cell standardized. Meanwhile, a duplicate cell may be substituted, whose case interchanges with the original, so that only two connecting leads need be secured to binding posts.

A small dry cell is used to furnish current for the main circuit. This cell is called "705 Eveready," and can be purchased in any electrical supply store.

Current Requirements

Nearly all portable potentiometers have a drum wire of low resistance measuring about 20 ohms. Consequently, to obtain sufficient "drop" or potential difference between its extremes, a comparatively large current is necessary. Therefore, the dry cell which furnished this current is constantly falling off in emf., due to polarization, and by use is rapidly exhausted. Furthermore, the current does not remain steady for any length of time and the rheostat requires constant resetting to keep the instrument in balance.

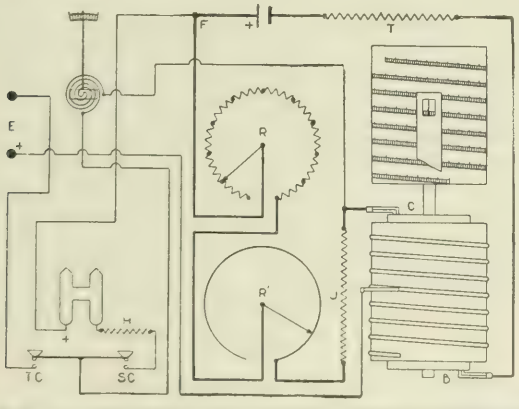

FIG. 5. DIAGRAM OF BROWN POTENTIOMETER

In this new potentiometer (Fig. 5), the drum wire has a resistance of 140 to 150 ohms, and the total instrument resistance for 50 millivolts is approximately 4,175 ohms, including the resistance of the rheostats. This is gradually reduced, by regulating the rheostats, to a minimum of about 3,400 ohms, when the dry cell is exhausted and must be renewed. The emf. of the dry cell is from 1.5 to 1.2 volts, according to its condition, and the current required to operate the potentiometer is never more than 0.00036 amp. or about one-tenth the current required to operate potentiometers of the ordinary portable type. The result is that the dry cell will have a long life (from three to six months, according to condition), which is of course an advantage; but what is of far greater importance is the fact that the current drawn from the dry cell is so small that the cell will not polarize and will give a practically constant current, subject only to temperature changes. Consequently the potentiometer, after being balanced against the standard cell, will remain in balance for hours without readjustment. Hence a large number of tests can be made in succession with the absolute certainty that there will be no errors introduced due to change in the potentiometer current.

Galvanometer

In the construction of any instrument in which the opposition or "zero" method is employed, a sensitive galvanometer is indispensable, in order that it will respond to minute changes in current. The galvanometer has no suspension fibers and the movable coil does not turn with an erratic motion, dance or vibrate. It is positive in its indications as well as aperiodic in action. Its resistance is approximately 150 ohms.

Sensitivity

If an electromotive force of one volt is impressed on a resistor of one megohm (1,000,000 ohms) the flow of current will be one-millionth ampere, or one microampere. This current, when passed through the movable system of the Brown portable galvanometer, will cause a deflection of 2.8 mm. Stated differently, the galvanometer has a guaranteed sensitivity of 2.8 megohms (10^{-6} amp.). These remarkable results are obtained by using tungsten alloy magnets, a concentrated field and a movable system wound with special enamel-insulated aluminum wire. The weight of this movable system is so slight that it is unaffected by mechanical jars in transportation, the pivots remaining sharp under all conditions, with no reduction in sensitivity.

Automatic Compensation, Single Scale

A single scale potentiometer intended exclusively for a certain type of thermocouple is calibrated in temperature degrees, either Centigrade or Fahrenheit or both, and may be automatically compensated for temperature changes in the cold ends of the couple. But such an instrument can be used only in connection with the type of thermocouple for which it has been adjusted and cailbrated.

Philadelphia, Pa.

Vegetable Oil for Italy

Recent inquiries have been coming to Japan for vegetable oil, due to decrease of imports from Holland, and some contracts for export to Italy have already been consummated. A considerable quantity of vegetable oil was shipped by the N. Y. Y. steamer Wakasa Maru, which sailed for Genoa with the Japanese shipping delegates on board. It is said that the N. Y. Y. contemplates in case of regular shipment of oil to Italy, sending its ships to Genoa.

Chart of Viscosities in Different Systems

By H. G. Nevitt

VISCOSITY is variously defined as the degree of fluidity of a liquid, its internal friction or shearing modulus. This property is an important one in many liquids, and the primary one in a lubricant, as it is the most important indication of its fitness for that purpose. Viscosity is commonly measured by an instrument which allows the liquid to flow through an orifice, the degree of viscosity being given by the time taken by a fixed quantity of liquid to flow through.

Obviously in the case of any viscosimeter, where the time of flow or similar direct reading is taken, the viscosity factor is a function of the instrument as well as the liquid. Attempts to get away from this have been made by getting a comparative viscosity, as in the Engler method, where the ratio of the time of flow of the liquid to that of water is taken, or by obtaining the actual shearing force, or absolute viscosity, which is a function of the liquid only.

At the present time there are a number of instruments and systems used, but the following are the most common:

The Saybolt Universal, or time on Saybolt instrument.

The Redwood, or time on the Redwood instrument.

The Engler number or comparative time of flow, with water equal to unity.

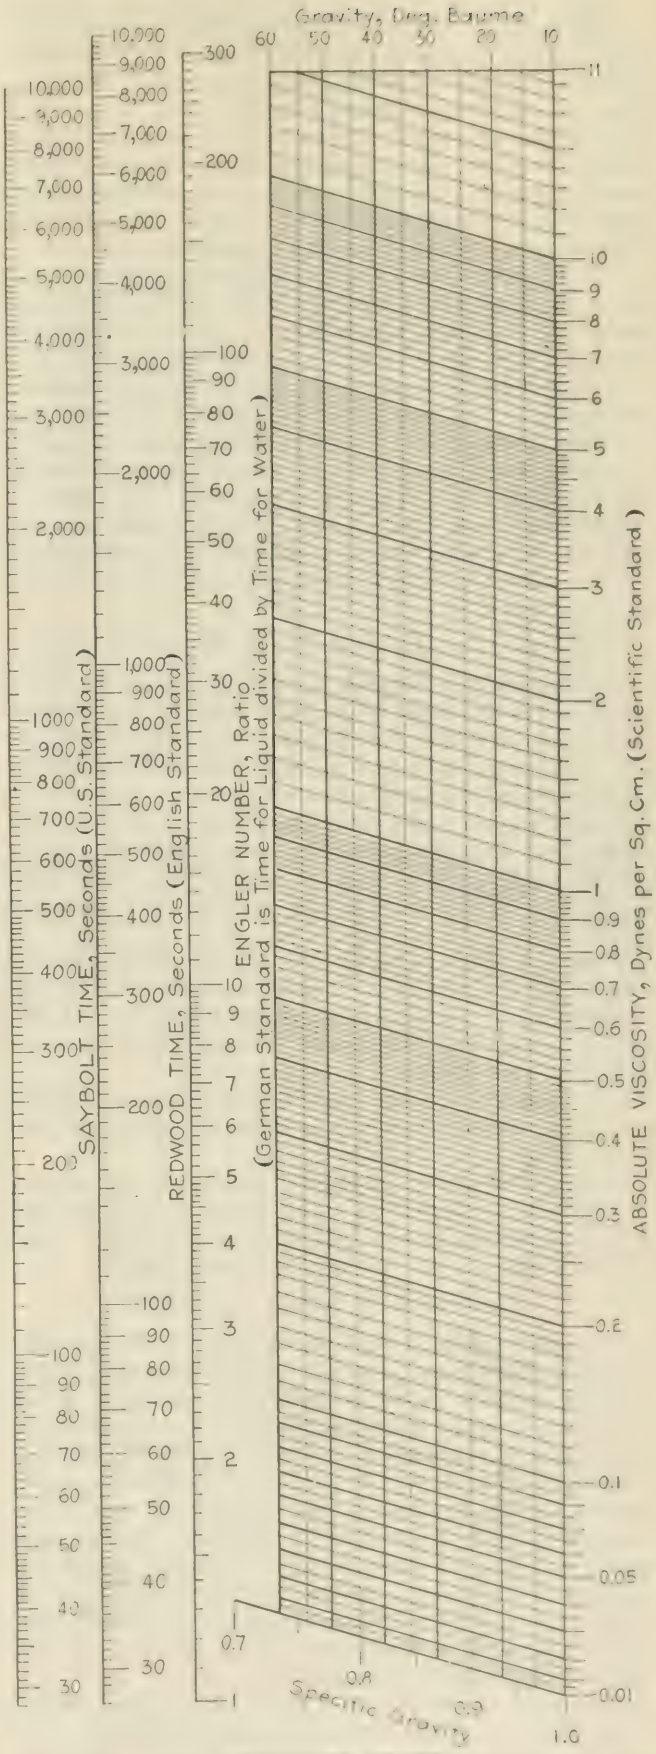
The Absolute Viscosity in c.g.s. units. This involves the specific gravity as well as the time of flow on an instrument, as two liquids of the same time of flow but of different densities have different internal shearing resistances. However, as most liquids being compared generally have about the same specific gravity, this does not cause trouble.

The confusion that may result from the number of systems in use is apparent. This is especially true of the export trade, and when dealing with foreign authorities and data on liquids. In the petroleum industry especially, where viscosity is an important and controlling factor in handling some of the distillation fractions, the difficulties of knowing more than one system or changing over become considerable, if a large number of distillations are being compared. In consequence we are almost forced to some quick method of comparison, and the graphical seems by far superior.

To do this the common method of plotting the various values reduced to equivalent scales, so the value in any other system is read opposite the quantity on the given system, is used. The correction for the specific gravity in reducing to the absolute system also presents no difficulties graphically.

Any basic scale of laying off the values on the primary system may be chosen, but the logarithmic seems best for several reasons. It covers a wide range of viscosities without too small a scale for reading in the common range of values. It also makes the most probable error of reading constant in percentage, rather than in amount. This is also an advantage in that the error of determination is also approximately constant in percentage, so that inconsistencies in reading the chart are avoided. By then plotting the co-ordinate lines for specific gravity to a logarithmic scale also, the lines for variation of absolute viscosity with specific gravity become straight and have a constant slope.

Tampico, Mexico.



VISCOSITY CHART

To obtain equivalent viscosities, read horizontally across the scales. A sheet of paper cut square makes an excellent guide. Example:

An oil of 30 deg. Bé. gravity has a viscosity of 200 on a Saybolt instrument. Read Redwood equivalent as 185, Engler as 5.24 and absolute as 0.328 from the chart, using the 30 deg. Bé. line for the absolute intersection.

The German Works Councils Act

A RECENT issue of the British official *Labor Gazette* contains the following résumé regarding the provisions of the German works councils act:

A works council act (Betriebsrätegesetz) was passed on Jan. 18, 1920, in order to guarantee the general economic interest of workers (manual and non-manual) in relation to their employers and to assist the employers in carrying out the aims of their undertakings.

The term "worker" (Arbeitnehmer) covers all manual and non-manual workers with the exception of members of the employer's family. It does not include persons whose employment is not mainly for profit.

Works councils must be set up in all establishments employing as a rule at least twenty workers. In smaller establishments a works steward must be elected. A special works council for outworkers must be set up when twenty or more are employed. In order to guarantee special economic and social interests, separate councils for manual and non-manual workers must be set up wherever both classes are represented on the works councils.

Council Members Elected by Secret Ballot

Members of the councils are to be elected by direct and secret ballot according to the principles of proportional representation for the year; they shall be eligible for re-election. All workers, male and female, of eighteen years and over, in possession of civil rights have the right to vote. All with the right to vote who are twenty-four years of age and over, who are not learners and who have been at least six months with their employer and three years in the industry, are qualified for election.

Rules are laid down for election procedure, and the Federal Minister of Labor, in agreement with the Federal Council and a committee of the Reichstag consisting of twenty-eight members, is empowered to issue administrative regulations.

If a works council has nine or more members it must elect from its own members a works committee of five persons.

Provision is made for (1) a central works council in addition to, or (2) a joint works council instead of individual works councils when interdependent establishments are owned by the same firms, etc.

Functions of Works Councils

In section 66 it is laid down that it shall be the function of the works council to help the management to secure efficiency; to protect it from unauthorized interference, and, failing agreement in disputes, to appeal to the conciliation committee or to an arbitration board to be agreed on; to fix or modify, in agreement with the employer, the conditions of service; to promote a good understanding between workers and employer and to maintain the workers' right of forming associations to take measures to prevent danger to health and accidents; and to co-operate in the administration of pensions, housing, or other welfare schemes attached to the establishment.

The works council has the right to require the employer to give to the works committee information as to all the transactions of the establishment which affect the contract of service and the activity of the workers (provided no business secrets are endangered or legal regulations contravened), and to show the wages, books, and give other information necessary for carrying out existing collective agreements. The employer must supply a quarterly report on the position and progress of the undertaking and of the industry in general, as well as of the output of the establishment and the expected demand for labor.

Penalties of the Act

Any person who with intent to deceive the workers shall give wrong data or conceal correct data in reports on the financial position is liable to imprisonment not exceeding one year and to a fine not exceeding 10,000 marks, or to either of those penalties. Any person disclosing confidential information given to him as a member of a works representative body is liable to a fine of not more than 1,500 marks or to imprisonment; if convicted of intention to gain financial advantage or to injure the employer, heavier penalties may be imposed.

Should the engagement or dismissal of a considerable number of workers become necessary, the employer must as soon as possible discuss with the works committee or the works council the nature and extent of the necessary changes and the possibility of avoiding hardships.

The functions of the manual and non-manual workers' councils are of a more specialized character. They include, among many others, the laying down of guiding rules for the engagement of workers in their group in the establishments and co-operation in carrying out the regulations as to their discharge.

The engagement of a worker must not be conditional on his political, military, religious, or trade-union views, or on his belonging or not belonging to a political, religious, or occupational union or to a military association. The rules must not prescribe that the engagement shall depend on belonging to a particular nationality.

Appeals Against Discharges

Provision is made for appeal by the councils against the engagement or discharge of workers to the competent conciliation committee or an arbitration board. Discharge without a statement of the reason for it is one of the grounds of appeal.

If the appeal against dismissal is held to be valid, the employer must either offer reinstatement or give compensation for dismissal. The amount of compensation is fixed at the rate of one-twelth of the earnings in the last year for each year of service, but should not in all exceed six-twelfths. Should the worker accept reinstatement, the employer must pay him his wage or salary for the period between dismissal and reinstatement. Should the worker refuse re-employment he is entitled only to wage or salary for the period between the date of his discharge and the date of the conciliation committee's award.

Before giving notice of dismissal to a member of a works representative body, or before transfer of such a worker to another establishment, the employer must obtain the consent of the works representative body.

Membership List of American Chamber of Commerce in Mexico

A printed list of the members of the American Chamber of Commerce of Mexico City has been issued and can no doubt be obtained on application, addressing American Chamber of Commerce of Mexico, at 2A Motolinia 23, Mexico City, Mexico.

Use of Paranitraniline to Standardize Solutions of Sodium Nitrite

By William H. Bell*

THE usual method for the analysis of aromatic amines, such as anthranilic acid, amino G salt, benzidine, dimethylparaphenylenediamine, etc., consists in the diazotization of a definite amount of the aromatic amine by means of a standard solution of sodium nitrite, the end point being ascertained by means of starch-iodide paper. The usual procedure is to use an M/1 (M = molecular weight in grams per liter) solution of sodium nitrite, which is allowed to fall, drop by drop, into a hydrochloric acid solution of the amine. It is customary to dilute the amino solution to about 500 c.c., and to maintain it at a temperature of approximately 15 deg. C., but these factors vary with each individual compound. In some cases, such as aromatic amines containing sulphonic or phenol groups, the amine is first thrown into the sodium salt, the solution cooled, and while stirring vigorously, the compound is precipitated by means of hydrochloric acid. Since the particles come out of solution in fine condition, diazotization is greatly facilitated. Again, in other cases, it is necessary to heat the amino compound with hydrochloric acid, in order to secure solution.

Another factor which varies considerably is the temperature—some compounds must be diazotized as low as 5 deg. C., while others may be safely diazotized as high as 40 deg. C.

In every case, however, the solution is constantly stirred by means of an automatic stirrer, and the sodium nitrite is allowed to drop at such a rate that is used up very quickly. The latter is, of course, ascertained by removing a drop of the solution and testing it with starch-iodide paper.

The Lunge Method

The ordinary procedure in use for the analysis of aqueous solutions of sodium nitrite is based upon the method of Lunge. His method consists in adding a definite volume of sodium nitrite solution to an excess of $KMnO_4$ solution, which has been acidified with sulphuric acid. Sufficient time is allowed for all the nitrite to be oxidized to nitrate, then an excess of KI solution is added. Iodine is liberated and the latter is titrated with sodium thiosulphate, starch being added as indicator.

There is no question as to the accuracy of Lunge's method. However, in the diazotization of aromatic amines, there is a constant source of error, due to the fact that free nitrous acid must be present before an end point is reached. Furthermore, if the sodium nitrite solution had been standardized against an aromatic amine of definite purity, the end point in standardization would contain the same error as is met in the diazotization of unknowns, and the two sources of error, being practically the same, would tend to neutralize each other. The chief source of trouble in applying this method has been in securing an aromatic amine of definite purity. Paranitraniline serves excellently for this purpose, since it can easily be secured in pure form as long yellow needles, of correct melting point, and which I have found by a number of methods to analyze 100 per cent.

*Baldwin Fellow, University of Cincinnati; formerly Chemist, the Ault & Wiborg Co.

Paranitraniline Method

In standardizing an M/1 solution of sodium nitrite, the following procedure is recommended: Dissolve 70 g. of sodium nitrite per liter of distilled water. This will give approximately an M/1 solution. Weigh out 3.4517 g. of paranitraniline, wash into a 600-c.c. beaker, add 10 c.c. conc. HCl, and 100 c.c. water. Heat to effect solution, then add ice and water until temperature is approximately 15 deg. C., and volume of liquid about 350 c.c. Start automatic stirrer, and add sodium nitrite solution, drop by drop, from a burette. If solution is exactly M/1, just 25.0 c.c. of $NaNO_2$ will be required. When 22 or 23 c.c. of solution has been used, it is necessary to test the solution very often for excess nitrous acid. It is best to do this by removing one drop by means of a glass rod and applying it to a piece of starch-iodide paper. When excess nitrous acid is indicated, shut off burette, and test frequently again for several minutes in order to be sure that permanent end point has been reached. Run two other samples of paranitraniline in the same manner, and use the average of the last two results.

$$\frac{25.0}{\text{No. of c.c. } NaNO_2 \text{ used}} = \text{Cor. Fac. for M/1 Solution.}$$

This method has been tested quite thoroughly and has been found quite accurate for the purpose. It is quicker and more convenient than Lunge's method.

Washington, D. C.

Peanuts and Peanut Oil Exports From China

Large quantities of peanuts and peanut oil are produced in the province of Shantung, China, and shipped abroad and to other parts of China. Customs returns show the exportation of the following from Chefoo and Tsingtao to foreign countries and various parts of China:

CHEFOO PRODUCTION IN PICULS

	1914	1915	1916	1917	1918
Peanuts	170,757	243,692	143,557	126,729	78,219
Peanut oil	98	6,834	3,692	2,102	5,326

TSINGTAO PRODUCTION IN PICULS

	Unshelled Peanuts	Shelled Peanuts
1909	336,635	214,000
1910	668,991	
1911	797,058	109,858
1912	829,419	230,987
1913	1,044,000	147,103
1914	964,676	75,573
1915	101,986	57,903
1916	533,601	234,541
1917	410,869	248,387

During the European war, higher freight rates and scarcity of ships caused a decrease in acreage devoted to the cultivation of peanuts, with a corresponding shortage in production and falling off of exports. With the restoration of peace, however, exports have been increasing.

The prices of peanuts and peanut oil are subject to considerable fluctuation. In the spring of 1913, peanuts were quoted at $8.70 (Mexican) per picul at Tsingtao, but just prior to the outbreak of war in 1914 the price fluctuated between $5.50 and $8. At present, however, the price is fluctuating between $4.80 and $9.80.

Peanut oil was quoted at $9.90 per picul at Tsingtao in 1914, but it rose to $19.50 in January, 1918, owing to the keen demand for the oil.

Peanuts and peanut oil are produced in all parts of China, but peanuts produced in Shantung province are well known for their superior quality and are in active demand in both Europe and America.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Indigo and Vegetable Extract Dye Compound.—Indigo paste combines with about eight times its weight of freshly prepared vegetable extract (such as logwood, quebracho or cutch) to form a compound which is readily soluble in soap solution or alizarine oil. This solution dyes yarn or cloth a reddish brown which is developed to the characteristic indigo blue by after-treatment with iron, copper or nickel salts, preferably a solution of copper oxide in ammonium carbonate. Unlike ordinary reduced indigo liquor, the blue color does not develop upon exposure to the atmosphere. JOHN W. FRIES, of Winston-Salem, N. C., has found that oxidized vegetable extract may be reduced by yeast fermentation so that it yields as good results as the freshly prepared extract. The compound may be marketed in powder or paste form. For use it is simply dissolved in 1 per cent soap solution. (1,341,637; June 1, 1920.)

Detonating Fuse.—Detonating fuse or cordeau is ordinarily made by filling a metallic (usually lead) pipe of, say, 1½ in. diameter with molten trinitrotoluene. When the TNT has solidified the diameter of the pipe is reduced by passing through a series of rolls. TNT makes the most satisfactory cordeau, but unless the TNT is very pure, the cordeau deteriorates with age. WILLARD C. COPE, of Woodbury, N. J., has found that the addition of tetryl (2.4.6-trinitrophenyl-methyl-nitramine) increases the velocity of detonation of the cordeau and also prevents deterioration so that an inferior grade of TNT may be used. The proportion of tetryl may vary from 2 to 75 per cent. (1,341,705; assigned to E. I. du Pont de Nemours & Co.; June 1, 1920.)

Caustic Mixtures.—Owing to the necessity of shipping caustic soda in airtight iron drums, JOHN ARMSTRONG, of London, England, proposes to ship a mixture of dry slaked lime and sodium carbonate, which will give a solution of sodium hydroxide when stirred with water, calcium carbonate being precipitated. The mixture is permanent in reasonably dry air and may be put up in paper containers. (1,342,148; one-half assigned to Patent Corporation, Ltd., of Liverpool; June 1, 1920.)

Sulphuric Acid Chambers of Acid-Proof Masonry.—The reactions in sulphuric acid chambers generate large amounts of heat which in lead chambers must be dissipated by radiation. Since the radiating capacity of the chamber is practically a fixed quantity, a rather definite limit of production is set beyond which the chambers fail to function properly. It has long been recognized that the reaction velocity in the chamber process could be increased by a vigorous mixing of the gases, causing them to impinge upon surfaces wet with acid. However, forms of construction hitherto proposed have involved the use of lead so that increased construction and maintenance costs overbalanced the advantages due to increased reaction velocity. ELDON L. LARISON, of Anaconda, Mont., constructs the chamber of acid-proof masonry. The heat of reaction is removed by continuous circulation of sulphuric acid over the tower packing. The concentration of the acid is so regulated as to avoid the absorption of material quantities of nitrogen compounds. By employing for every 2 lb. S in the form of SO_2 an amount of nitrogen compound equivalent to from 1 to 2 lb. $NaNO_3$, it has been found that the usual chamber reactions are accelerated about thirteen times. In lead chambers the ratio is 4 lbs. to 1 lb. $NaNO_3$ equivalent. (1,342,024; June 1, 1920.)

Process of Treating Copper-Bearing Sands.—In the leaching of copper-bearing sands with solutions containing ammonia, difficulty has been encountered in removing the occluded or adsorbed ammonia from the leached material. The loss of solvent has been a source of expense and a cause of low recovery of copper. The ammonia cannot be completely removed by washing with water. A better recovery may be obtained by passing steam through the bed of leached sands and condensing the effluent vapors. The latter method is expensive and entails the use of heavy apparatus to withstand pressure and the apparatus must be made tight to avoid loss.

C. H. BENEDICT and H. C. KENNY of Lake Linden, Mich., avoid the drawbacks attendant with the use of steam under pressure by admitting the steam at atmospheric pressure above the bed of sand and causing it to flow downwardly through the bed by maintaining a partial vacuum beneath the bed. There is some condensation of the steam; this is withdrawn and used as a wash in the treatment of fresh batches of sand. The application of steam is continued with the condensation of effluent vapors until the ammonia content in the condensate falls to a predetermined minimum. The application of steam is then discontinued and hot water distributed uniformly over the upper surface of the bed, the partial vacuum being maintained. The water vaporizes at the diminished pressure as it percolates through the heated sand and the resulting steam entrains the last recoverable trace of adsorbed ammonia. The utilization of the residual heat in the sand avoids the heat losses which obtain where highly heated sands are run directly to waste. (1,335,474; March 30, 1920.)

Process of Recovering Cobalt.—The process consists in roasting the ore in the presence of sulphuric acid, extracting the soluble sulphates with water, precipitating the impurities, such as iron, arsenic and copper, with calcium carbonate, removing the precipitate by filtration, precipitating the cobalt in the filtrate with lime in amount sufficient to form a basic insoluble sulphate. The cobalt is recovered by electrolysis, of a sulphuric acid solution, with insoluble anodes, the electrolyte being maintained at less than 1 per cent acidity by neutralizing the liberated sulphuric acid with the basic sulphate obtained as described. In case copper is not completely precipitated when the solution is treated with calcium carbonate, it may be separated from solution by precipitation on cobalt or removed in a special cell using low voltage. Nickel if present will follow the cobalt through the various steps of the process and, if desirable, can be separated by any of the usual methods. (1,336,765; MARVIN J. UDY of Kokomo, Ind.; assigned to Haynes Stellite Co.; April 13, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent office, Southampton Buildings, Chancery Lane, London, England.

Antimony Pigments.—An antimony pigment suitable for vulcanization is produced by decomposing a mixture of an antimony salt with alkali waste liquor by means of an excess of sulphuric or hydrochloric acid. Any proportion of the alkali waste liquor may be replaced by the product obtained by boiling lime with sulphur. (Br. Pat. 138,137—1919. E. F. MORRIS, Roby, near Liverpool, March 31, 1920.)

Synthetic Tanning Products.—Formaldehyde condensation products are obtained by condensing formaldehyde (or substances yielding it) with mixtures of naphthylamine sulphonic acids and aromatic monohydroxy compounds containing acid salt-forming groups, at 60 to 80 deg. C., in the presence of a little sulphuric acid. The resulting solutions may be used directly for tanning, after neutralizing by alkali the free sulphuric acid present. Products of increased tanning value are obtained by neutralizing the free sulphuric acid in the solutions by hydroxides of metals whose salts have tanning properties, as chromium, aluminum or iron, with or without neutralizing the sulpho groups by alkali. (Br. Pat. 138,796—1919. A. G. BLOXAM, DURAND & HUGUENIN, Basel, Switzerland, April 14, 1920.)

Cellulose for Paper Making.—In the preparation of cellulose for paper making from fibrous plants such as maize, alfalfa, dwarf palm, papyrus, etc., the stalks and leaves are cut up, crushed and washed, and then treated by steam at 2 to 3 kg. pressure for one hour in a digester, condensation water being drained away and taking with it parenchymatous cellulose and soluble matters such as gums and pectates. The cellulose fibers swell up and the cement is partly dissolved. The drain cock is then closed and 13 per cent caustic soda is introduced and circulated by a Koerting injector, or by using a digester of the vomiting type, or other means, the operation being conducted for 3 hr. at 2 to 3 kg. pressure. The product is washed, broken in a beating engine or small mill, and bleached, and may be used for half-pulp paper, such as packing paper. Semi-chemical pulp may be obtained by substituting slaked fat lime for the caustic soda, and, by partial bleaching of the half pulp so produced, a pulp suitable for newspaper is obtained. Alkali materials may be recovered by evaporation and re-causticized by the methods usually employed in soda pulp mills. (Br. Pat. 138,911—1919. SOC. ANON. A. OLIER, Clermont-Ferrand, France, April 21, 1920.)

Phenol-Aldehyde Condensation Products.—Soluble condensation products are first obtained from phenols and aldehydes by heating with catalysts such as sodium salicylate or ammonium sulphocyanide, and are then converted into insoluble products by heating with catalysts such as sodium cyanide or ammonium chloride. An example is given of the treatment of phenol and formaldehyde. The products may be used in the manufacture of varnishes, enamels, plastic compositions, insulating materials, combs, phonograph disks and cylinders, etc. They may be mixed with cellulose esters, sugars, albumens, triacetin, tartaric esters, eugenol, camphor, coloring matters, etc. (Br. Pat. 139,147—1919. L. JALOUSTRE, Z. KHEIFETZ and M. WARCHAVSKY, Paris, April 21, 1920.)

Oxyaldehydes.—Oxyaldehydes and their ethers are produced by the interaction of a phenol or its ether, formaldehyde, and a nitroso compound. The preparation of vanillin by treating guaiacol and formaldehyde with p-nitrosodimethylaniline is described. Anisol aldehyde, pyrocatechin aldehyde and salicylic aldehyde are also referred to. (Br. Pat. 139,153—1919. A. WEISS, Lyons, France, April 21, 1920.)

Sulphur Dioxide From Slag.—Sulphur dioxide sufficiently concentrated for the production of a sulphuric acid is obtained by oxidizing the sulphides in liquid blast-furnace slag by passing a limited amount of air or oxygenated air over or through the slag, or both, or by adding an oxidizing agent such as calcium or magnesium sulphate to the slag, or by both adding such an agent and treating with air. The oxidizing agent may be pre-heated and may be used in molten condition. For this purpose, calcium sulphate may be fused with a small proportion of a flux such as sodium chloride or calcium fluoride. The treatment of the slag is such as not to cause solidification. For instance, the air may be blown through the slag, and the hot air arising therefrom may be passed over the slag as it runs along a covered channel in counter-current. The liberation of the sulphur dioxide may be facilitated by stirring or by blowing in heated air, but the quantity of air should not in any case be such as to yield a product containing less than 4 per cent of sulphur dioxide by volume. The slag may be treated in a slag-pan provided with a hood, dip-pipe and gas outlet, or in one of several covered slag sumps disposed in the slag run. The treated slag is suitable for the manufacture of slag cement, slag wool, etc. (Br. Pat. 139,172 and 139,173—1919. L. H. DIEHL, Berlin, April 21, 1920.)

Cellulose Acetates.—Cellulose acetate is formed by adding a halogen, such as chlorine or bromine, to a mixture of cellulose, acetic acid and acetic anhydride. A halogen acetic acid is formed and acts in its nascent state as a condensing agent. When the action is completed (after about 2 hr. at 70 deg. C.), further esterification is brought about by the addition of a strong acid such as sulphuric or chlorsulphonic acid. The solution may be used for directly making films, artificial silk, horsehair, etc., or the ester may be precipitated. The halogen has also a hydrolytic action upon the cellulose and this action may be varied by varying the temperature (up to 80 deg. C.), the amount of halogen or the length of time of the action. A further hydrolysis may be effected by adding dilute acetic or other acid, formaldehyde or hydrogen peroxide. Esters are obtained which yield solutions of low viscosity in acetone, chloroform, or in mixtures of acetone and alcohol, or of acetone, alcohol and benzol. (Br. Pat. 139,232. J. O. ZDANOWITCH, London, April 28, 1920.)

Chlorination and Sulphonation.—The sulphonation or chlorination of aromatic compounds, such as benzene, toluene or phenol, is effected by atomizing the aromatic compound and sulphuric acid or liquid chlorine into a chamber, from which the mixture passes to a second chamber provided with heating or cooling coils; the product is drawn off from the lowest chamber. The production of benzene monosulphonic acid and chlorbenzene is described. In the case of chlorination, the second chamber contains a catalyst, such as aluminum chloride or ferric chloride. (Br. Pat. 140,007—1919. H. N. MORRIS, Manchester, May 5, 1920.)

Current Events
in the Chemical and Metallurgical Industries

Hearing on Minerals Separation-Miami Contempt Proceedings

At Wilmington, Del., on June 15, a motion to dismiss the petition of Minerals Separation, Ltd., seeking to punish Miami Copper Co. for contempt of court, was heard. The petition also asked an extention of injunction to cover the present operations of that company.

The Miami company held that such a petition for contempt and extension of injunction was not warranted by the facts. It took the ground that such action, under the circumstances, was not the proper procedure. Such action by the court before the Miami company's witnesses had also testified before the Master, it was claimed, would be unfair to the defendant, since the processes enumerated in the petition were the very ones to which so large a part of the testimony already given before the Master referred. Judge Bourquin's decision in the Butte & Superior contempt proceedings (CHEM. & MET. ENG., June 16, 1920, pp. 1099 and 1131) was cited, Miami claiming its case analagous.

Minerals Separation eventually admitted that Miami should have an opportunity to cross-examine Minerals Separation witnesses. Much of the arguments of Minerals Separation counsel was devoted to emphasizing the violence of agitation in various steps of Miami process. Miami counsel, however, made their contention strictly one of procedure.

Miami Petition to Reopen Case Denied

The United States Circuit Court of Appeals of Philadelphia has declined to reopen the case of Minerals Separation, Ltd., vs. the Miami Copper Co. on petition of the latter to admit newly discovered evidence. The order of the court in this matter was filed June 18. While it declines to reopen the case, the court states that it expresses no opinion as to the relevancy and competency of the subject matter of the Miami petition on questions arising in the accounting before the Master.

Large Pulp and Paper Combination Formed

A big combination of pulp and paper manufacturers of Canada has been formed by the merger of the Riordon company of Montreal and the Edwards, the Bronson, and the Gilmour & Hughson companies of Ottawa. This merger, which is a $60,000,000 affair, will control greater pulp wood and timber limits than any other single management in the Dominion.

It will control 12,000 square miles of timber lands in the Ottawa River Valley, containing about 25,000,000 cords of pulp wood, 1,200,000,000 ft. of standing pine and other woods, in addition to water facilities for generating 150,000 hp. The tract is said to be the largest known remaining source of pulp wood and pine in Canada. The pulp and paper output of the new corporation as estimated will be 150,000 tons, while 125,000,000 ft. of pine will also be cut.

Crown-Willamette Installs New Sulphurous Acid System

The Crown-Willamette Paper Co., operating large mills at Camas, Wash., and West Lynn, Ore., and also, under the name of Pacific Mills, Ltd., another mill at Ocean Falls, B. C., has installed the Jennsen tower system for the production of sulphurous acid at the Camas plant. This is the first use of the new system in paper mills on the Pacific Coast. The feature of the Jennsen system consists of high concrete towers which are filled with raw limestone, calcined dolomite being used in this case. Through this rock sulphur dioxide is passed in solution. Under the older and more expensive process, bubbles of sulphur dioxide were passed through a vat containing milk of lime. Efficiency and economy of operation and a greater uniformity of product are advantages of the Jennsen system. If the new process proves up to expectations, it will be installed in all three plants operated by the company.

Another innovation recently inaugurated by the Crown-Willamette Paper Co. is the bringing of sulphur by water instead of by rail from the Gulf of Mexico to Portland, Ore., for distribution to the two plants near that city. The sulphur, as well as the lime rock, is handled entirely in bulk. The rock is to be brought from Puget Sound to Portland by a fleet of sea-going barges.

This same paper company has just purchased 17,500 acres of timber land in Necanicum County, Ore., which cruises a total of 650,000,000 ft. of standing timber. Spruce and hemlock comprise 88 per cent of this timber. The supply is sufficient to keep the mills running for twenty years.

Committee Urges Development of Alaska's Pulp Wood

In a special report to the Secretary of the Interior the Alaska Advisory Committee urges that an intensive campaign be made for the development of Alaska pulp wood. The committee is charged with the duty of searching out ways to better conditions in Alaska and particularly to stimulate industries so as to provide tonnage for the new Alaska railroad.

The committee points out that an ultimate possible annual production of 2,000,000 cords of pulp wood may be obtained from Alaska timber and recommends that the Government launch an intensive campaign for its development. Attention is called to the fact that the water-power resources of Alaska can be used to advantage in this development.

The report declares that 60 per cent of the population of the territory in the past has been directly or indirectly employed by the gold mining industry. To the decline in gold mining is laid the principal blame for Alaska's loss in population and the discouragement of her residents. Thus the maximum prosperity of the territory must await a revival of gold mining.

Water-Power Bill Signed by the President

After twelve years of consideration, Congress at last has adopted a water-power policy and has prescribed exact conditions under which the nation's white coal may be used. The final step, so far as Congress is concerned, was taken May 28 when the Senate, by a vote of 45 to 21, approved the conference report on the water-power bill. The bill was signed by the President prior to June 11 under a formal opinion by the Attorney-General that the adjournment of Congress does not deprive him of the ten days allowed by the Constitution for the favorable consideration of a measure.

While much of the delay in securing this legislation has been due to the difficulty of determining in advance a policy in a matter which has so many ramifications and intricacies, the main conflict has been between those who were emphasizing what they conceived to be necessary in the public protection, as against those who were struggling to secure a law of sufficient liberality to attract capital. In the enactment of some of the so-called conservation measures, the conservation idea was so emphasized that capital could not be interested, with resultant stifling of development.

Believed Capital Will Be Attracted

The water-power bill, just signed, contains many restrictions, but it is believed that capital can be attracted to water-power development under its provisions. It is realized that modifications are certain to be made in the light of experience, and capital apparently is hopeful that it will have an opportunity to make a fair rate of return on investment. On the other hand, in conservation circles, the opinion seems to prevail that the bill is unnecessarily liberal and that the last of the great national resources is being disposed of without proper protection of the interests of the general public.

Much Power Gone to Waste

During the long wrangle over the water-power policy, it is admitted that the country has suffered very large losses through allowing water power to go to waste. Senator Wesley L. Jones, of Washington, the chairman of the Senate Committee on Commerce, under whose jurisdiction the bill comes, estimates that the delay in fixing fair and reasonable terms for the use of water power resulted in the United States being found at the beginning of the World War with 5,000,000 hp. of developed hydro-electric energy, instead of 20,000,000 hp. which it should have had. Caught in the pinch of war, Senator Jones points out, the nation was soon short of coal, short of oil and short of power. Half a billion dollars had to be expended within two years in the erection of steam power plants, just at a time when the capital, labor and material were most needed for other purposes in the prosecution of the war.

Estimates as to the potential water power in the United States vary greatly, but the calculations of the United States Geological Survey place the minimum potential water power of the country at about 35,000,000 hp. and the assumed maximum at something over 65,000,000 hp. This estimate does not take into consideration the increases in horsepower which it will be possible to obtain by providing for storage of water.

Commission to Administer the Act

The act is to be administered by a Federal Power Commission which is to be composed of the Secretaries of War, Interior and Agriculture. The direct administration of the law, however, falls upon an executive secretary. The commission is charged with forty-five specific functions or duties. It has administrative control over all power sites on the navigable waters and on the public lands and reservations of the United States. It is to have to do with the location, design, construction, maintenance and operation of power projects upon such sites. Under certain conditions it must regulate financial operations and fix rates for service, to say nothing of making physical valuations of properties. In addition, the commission is charged with general investigations covering a wide field.

Specific Functions of the Commission

Among the specific functions of the commission are the following:

To issue licenses for power projects and transmission lines on navigable waters, public lands and reservations of the United States.

To investigate and approve all contracts for power made by a licensee which will extend beyond the termination of the license.

To prescribe rules for, and to fix annual license charges and to determine the relation of such charges to prices to consumers.

To hold hearings when desirable or necessary in connection with any application for a permit or license.

To see that projects are best adapted to a comprehensive scheme of improvement and utilization.

To require that project works be properly maintained and kept in efficient operating condition.

To keep in touch with conditions of the power market tributary to every development in order to require extensions as rapidly as conditions warrant.

To prescribe a system of accounting for licenses.

To prescribe rules for the establishment and maintenance of depreciation reserves.

To devise principles for the proper apportionment of surplus earnings to amortization reserves.

To regulate under certain conditions the amount and character of securities which may be issued for the financing of power projects.

To make valuation of all projects brought under license which have been constructed in whole or in part, prior to the application for license.

To determine the net investment and severance damages in the event that properties of the licensee are taken over by the United States at the termination of a licensed period.

Commission Also to Collect Data

In addition, the Commission is charged with the collection and reporting of data concerning:

The utilization of the water-power resources of any region to be developed.

The water-power industry and its relation to other industries and to interstate and foreign commerce.

The location, capacity, development costs and relation to water-power sites.

Whether the power from Government dams can be used advantageously by the United States for its public purposes and what is the fair value of such power.

To determine whether lands of the United States reserved as power sites may be open to entry subject to a reservation of the power rights of the United States.

Deterioration of structures and equipment for the purpose of establishing rates of depreciation and the amount of annual depreciation reserves.

Special Investigations to Be Made

In addition there are a number of special investigations which the Commission must make. One of these is to estimate the cost and economic value of generating hydro-electric power at Great Falls, on the Potomac River, near Washington. The opening up of the nation's water powers is expected to be of special stimulus to the chemical industry.

New Jersey Chemical Society Holds Meeting at Rutgers College

The June meeting of the New Jersey Chemical Society was held at Rutgers College, New Brunswick, by invitation of the Chemical Department, on the afternoon and evening of June 5, and, in spite of the heavy rain, a fair number of out of town members were present. The storm prevented inspection of the college farm, as well as the buildings and grounds, as had been planned, and the afternoon session was devoted to the series of motion pictures contributed by the Goodyear Tire & Rubber Co. of Akron, Ohio.

These showed the entire history, from the collection of the rubber latex, on the company's plantations in Sumatra, through each step in the manufacture, to the final inspection of automobile tires. It was an exhibit of the greatest educational value and intensely interesting.

After dinner had been served in the college dining hall, the evening meeting was begun by an address by Dr. Jacob G. Lipman on the uses of sulphur in agriculture. After showing that the sulphur required by some crops was not present in some soils, Dr. Lipman described his own discovery of oxidizing bacteria on sulphur and finely ground phosphate rock in stable manure, which makes both the sulphur and phosphoric acid available.

A lecture was given by Dr. D. A. Lyon, of the Bureau of Mines, Washington, D. C., on the hydrometallurgy of copper illustrated by motion pictures of the extensive leaching and electro-deposition works at Ajo, Ariz. The processes employed have been so perfected that less than 2 per cent of copper makes the ore worth working, and the pictures gave a clear presentation of the operation of the project.

Awards Recommended by Minerals Relief Commission

A total of $1,238,451.12 has been recommended by the War Minerals Relief Commission for awards to claimants who produced chrome, manganese, tungsten and pyrites in response to the Government's war-time request or demand. This represents 32.6 per cent of the amount asked by the claimants. The total claimed in the cases in which these awards were made was $3,798,756.09. These figures include all claims in which recommendations have been made up to and including the week ended June 12.

Results of Government Nitrate Sales

Not more than 100 tons of the Government's nitrate of soda has been sold under the special statute enacted shortly before the close of the last session of Congress. The act authorized the sale of 100,000 tons of the Government's reserve of nitrate.

The nitrate is being offered at $88.90 a ton. At many points regular dealers in nitrate are making sales at lower figures. It is believed, however, at the War Department that the law at least had the effect of stabilizing the nitrate market.

All orders that have been placed are for ton lots. It is believed by Major J. H. Hunter, the officer in charge of the distribution, that the volume of buying will increase decidedly as the fact becomes more widely known that the War Department is conducting this sale of the material. At several of the points where the nitrate is in storage the Government price is lower than the price in the open market. It is not anticipated, however, that more than 20,000 tons will be sold under the act, which expires Oct. 20.

It is admitted that a larger volume of the nitrate would have been sold had it become available earlier in the year, but owing to the late season it could have been utilized to practically the same advantage had it been purchased when first available. For that reason some are of the opinion that the scarcity of nitrate is nothing like as great as was represented in Congress.

Procter & Gamble to Build Soap Plant in California

An option on about thirty acres of land in the San Francisco Bay district has been taken by representatives of the Procter & Gamble Co. upon which to build a new soap plant. At the beginning about 500 will be employed, but it is expected that double that number will be required shortly.

Personal

ELMER D. BALL, of the Iowa Agricultural College, has been appointed Assistant Secretary of Agriculture. For more than twenty years Mr. Ball has been engaged in investigation and research on agricultural problems or teaching in agricultural colleges.

WALTER M. BERRY, chemist in charge of the gas engineering section of the Bureau of Standards, has just started on a trip through the far West in connection with the Bureau work on gas quality standards and the activities of state public service commissions.

EDWARD CALDWELL, treasurer of McGraw-Hill Co., Inc., and treasurer and director of the McGraw-Hill Book Co., was tendered a dinner by his business associates in commemoration of his thirty years of service with these companies. Mr. Caldwell's first connection with technical journalism was as assistant editor of *Electrical World* in June, 1890. Among other activities he developed the book department of the McGraw Publishing Co. and was later instrumental in effecting the consolidation with the book department of the Hill Publishing Co., known as the McGraw-Hill Book Co. Among his early activities was that of business manager of *Electrochemical Industry*, the forerunner of CHEMICAL & METALLURGICAL ENGINEERING.

EUGENE B. CLARK has been made president of the American Ore Reclamation Co. and of the American Sintering Co., to fill the vacancy caused by the death of James Gayley.

SIDNEY CORNELL, chemical and industrial engineer, has moved his office from 1 West 34th St. to 80 Maiden Lane, New York City. He is spending the summer at Ogunquit, Me.

Dr. F. G. COTTRELL'S nomination as director of the Bureau of Mines was confirmed by the Senate shortly before the adjournment of Congress.

Dr. FREDERIC DANNERTH, who was retained by the C. Kenyon Co. of Brooklyn, N. Y., as consulting chemist, has recently declined the invitation to become head of the new laboratories. The new development department was planned and organized by him and this work was recently completed.

Dr. HENRY S. DRINKER announced his retirement from the presidency of Lehigh University, Bethlehem, Pa., on June 15, 1920. Dr. Drinker was graduated from Lehigh University in 1871, in which year he was one of the founders of the American Institute of Mining Engineers. Since that time he has been devoted to the service of the university, serving as secretary of the alumni, president of the alumni, alumnus trustee, trustee and president.

HENRY B. FABER received the honorary degree of Doctor of Science at Emory University, Atlanta, Ga., on June 10. Dr. Faber is a consulting chemical engineer in New York City, a member of the advisory board of the Chemical Exposition and until recently was actively connected with the Industrial Filtration Co.

EDGAR S. GENSTEIN, formerly engineer of tests, U. S. Naval Ordnance Plant, Charleston, W. Va., is now metallurgist for the Treadwell Engineering Co., Easton, Pa.

E. P. MATHEWSON has been appointed consulting metallurgist to the Granby Consolidated Mining, Smelting & Power Co.

STANLEY P. ROCKWELL has resigned his position as vice-president of Weeks-Hoffman Co., Syracuse, N. Y., to become metallurgist at Whitney Mfg. Co., Hartford, Conn., the change to take place July 1, 1920.

WILLIAM YOUNG WESTERVELT, consulting mining engineer, announces the removal of his office to the Fifth Avenue Guaranty Building, 522 Fifth Ave., New York City.

Obituary

OSCAR H. EBERT, treasurer of the Baugh & Sons Co. and the Baugh Chemical Co., with offices and plants at Philadelphia, Baltimore and Norfolk, died suddenly at his home in Baltimore on Wednesday, June 2, from an attack of acute indigestion, which brought on heart failure. He was ill only one day, and his death came as a great shock to his many friends in the fertilizer industry. Mr. Ebert was fifty-eight years old, and had been connected with the Baugh company more than forty-one years.

WHITFIELD P. PRESSINGER, of New York, vice president Chicago Pneumatic Tool Co., died June 10 as a result of complications following an operation. Mr. Pressinger was actively engaged in the pneumatic tool and allied machinery industry for many years. He was general manager of the Clayton Air Compressor Co. for seven years and became widely known through numerous activities in the American Society of Mechanical Engineers and the Compressed Air Society. He was born in New York City in 1871. In addition to the foregoing societies he was a member of the Sons of the Revolution, 7th N. Y. Regiment Veterans, F. and A. M., and the following clubs of New York City: Engineers, Lawyers, New York Athletic, New York Railroad, Columbia Yacht, and the Machinery Club.

HENRY E. SURFACE, a chemist of national authority on paper and valuation work, was killed in the disastrous wreck Wednesday, June 9, on the N. Y. Central Railroad, at Schenectady, N. Y. He is survived by a widow, Mary Hubbard Surface, and a son, Henry, Jr.

Current Market Reports

The Non-Ferrous Metal Market

New York, June 21, 1920.—A sharp drop in the London copper market caused a depression in this city. Large sellers quote 19c. for June-July deliveries, as before, but in outside market 17.75c. will buy spot copper, 18c. July-August. The tin market is a shade stronger than last week.

	Cents per Lb.
Copper, electrolytic	18.50
Aluminum, 98 to 99 per cent.	34.00
Antimony, wholesale lots	8.00
Nickel, ordinary	45.00
Nickel, electrolytic	45.00
Tin, Straits, spot	46.25
Lead, New York, spot	8.00
Lead, E. St. Louis, spot	7.75
Zinc, spot, New York	7.87½
Zinc, spot, E. St. Louis	7.50

OTHER METALS

Silver (June 17)	oz.	59.67
Cadmium	lb.	1.40@1.50
Bismuth, (500 lb. lots)	lb.	2.70@2.90
Cobalt	lb.	1.00
Magnesium (f.o.b. Niagara Falls)	lb.	1.65@1.85
Platinum	oz.	75@77
Iridium	oz.	300@400
Palladium	oz.	75@80
Mercury	75 lb.	70@75

FINISHED METAL PRODUCTS	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	34.00
Copper bottoms	38.00
Copper rods	38.00@40.00
High brass wire and sheets	30.25
High brass rods	25.00
Low brass wire and sheets	28.50
Low brass rods	29.00
Brazed brass tubing	43.25
Brazed bronze tubing	41.75
Seamless copper tubing	34.00
Seamless high brass tubing	33.00

SCRAP METALS	Cents per Lb. Buying Price
Aluminum, cast scrap	24.00@24.50
Aluminum, sheet scrap	24.00@24.50
Copper, heavy machinery comp.	15.00@15.50
Copper, heavy and wire	14.25@14.75
Copper, light and bottoms	12.50@13.00
Copper, heavy cut and crucible	15.00@15.50
Brass, heavy	9.00@10.00
Brass, light	7.50@8.00
No. 1 clean brass turnings	9.25@9.75
No. 1 comp. turnings	13.00@13.50
Lead, tea	5.00@5.50
Lead, heavy	7.00@7.25
Zinc, scrap	5.00@5.25

The Iron and Steel Market

Pittsburgh, June 18, 1920.

The course of the iron and steel markets has been quite uneventful in the past week. Buying of pig iron continues at a minimum, although there are occasional transactions. In steel there is free buying from the Steel Corporation, but limited business on the part of the independents, the explanation of the divergence being of course the wide difference in prices.

There is absolutely no snap in the market. Buyers take hold for only absolutely known requirements. They seem quite indisposed to consider any business except what it is certain they must place, and show signs of being on the lookout for a good opportunity to relax their efforts and await a more convenient season for activity. Almost throughout the industries there is a growing feeling that it is altogether too difficult to do business, costs being so high and performance on all hands so indifferent. Many observers insist the country needs "the rest cure" and will not be able to do good work until this corrective influence to the present ills has been applied. There is even, perhaps, a disposition on the part of some producers to apply the remedy, possibly in homœopathic doses, in the not distant future.

TRANSPORTATION CONDITIONS IMPROVING SLOWLY

Transportation conditions continue to improve, but very slowly indeed. Early in the week there was a backset in the matter of car supplies to some mills, due to the inauguration of the lake ore and lake coal pools, but this is only temperary, it is claimed, incident to starting the new system, which is expected to result in better service in moving coal to Lake Erie and bringing ore back, in proportion to the number of cars in the service.

In occasional instances steel mills are now shipping as much steel as they produce, but the general average is not as favorable as that, and outside the tin-plate industry there has been no noticeable reduction in the stocks of steel accumulated at any of the mills.

In tin plate excellent results have followed the preference accorded to box car supplies to tin mills, at the instance of the Interstate Commerce Commission. The tin-plate stocks at mills, fully 2,500,000 boxes, equal to the production of about one billion 2-lb. cans, or about one-seventh of the normal requirements of the fruit and vegetable packers, have been reduced to about 1,500,000 boxes, and the current make, at between two-thirds and three-fourths of capacity, has been shipped besides.

Production continues to increase by both blast furnaces

and steel works, and this despite the continued shortage of both coal and coke. The rates of production in both pig iron and steel are now nearly if not altogether up to the rates of last March, the highest since October, 1918, about 40,000,000 tons a year in pig iron and 45,000,000 tons in steel ingots.

Prices in general show no material change. Pig iron is firmly maintained by the furnaces, which experience no difficulty in securing full prices for such prompt deliveries as are called for, while there is little inquiry for second half to tempt price concessions even if sellers were so disposed. There are reports of a few consumers requesting postponements in deliveries, perhaps a reaction from the heavier shipments the furnaces are able to make as car supplies improve.

Prompt deliveries of steel products continue to show a declining tendency, but prompt deliveries have at no time comprised any large part of the turnover. The larger independent mills, able to make shipments in from two to four months, are firm in their price views, and naturally so since the business on books needs to be protected. It is recognized that in the easier general conditions that now obtain requests for postponements or cancellations are a possibility. As to the Steel Corporation, it pursues the even tenor of its way, with its Industrial Board prices, far below the prices of independents, tonnages being allotted from time to time to regular customers for shipment in the indefinite future, and following the shipment of tonnage already on books.

Labor Contest in Prospect

The uninteresting perennial, the sheet and tin plate wage scale settlement between the Amalgamated Association and the sheet and tin mills, about 40 per cent of the total number which sign tonnage wage scales annually with the association, has this year developed news, and a contest of such proportions as circumstances would permit is in prospect. The men had their usual demands for wage advances, and repeated the demand of a year ago for a 6-hr. instead of the thoroughly established 8-hr. shift, and from these demands there would probably have been the usual complete or nearly complete recession, but an entirely novel demand was made, that there should be inserted in the "preamble" to the scale a proviso that the manufacturers signing the scale book—the various tonnage wage scales, for iron mills, sheet and jobbing mills and tin mills are all printed in the one book—should thereby agree to allow the Amalgamated Association a free hand in organizing any other departments the various companies might have. This novel demand seems to have resulted from expectations on the part of the Amalgamated Association officials that the American Federation of Labor might undertake seriously to organize the iron and steel industry, and a feeling that the Amalgamated Association, while small now, is the "logical" body for doing any organizing if there is organizing going to be done. The manufacturers, of course, could not agree, and when it was proposed, at last Monday's session of the conference at Atlantic City, that an adjournment be had to the last week in June, the existing scales expiring June 30, the workers rejoined that if there were going to be an adjournment it would be to the first week in September, as the workmen desired a vacation and the manufacturers seemed to need time for reflection. Adjournment thereupon occurred promptly. Approximately 60 per cent of the sheet and tin mills, about a thousand all told, are non-union, including all those of the Steel Corporation, about 40 per cent of the total. The prospect is that the Amalgamated Association will be eliminated. Except in the sheet, tin plate and iron mill industries it has not been a factor since the Homestead strike of 1892.

The Chemical and Allied Industrial Markets

New York, June 18, 1920.

Developments in the chemical market during the past week have been few, with a slight falling off in demand as the most noticeable feature. As has been the case for some time back, more attention is displayed in locating certain of the more active items than in the actual price that is being asked. Among the *acids* which have been generally scarce for some time fair-sized offerings of *sulphuric*, 60 deg., at \$14@\$19 per ton, in tank cars, have been made, and there is also 1,200 tons of 66-deg. available for prompt shipment from Nitro, W. Va., quoted at \$23@\$26 per ton, sellers' tanks. *Acetic acid*, glacial, is easier with \$16.50 per cwt. as the prevailing quotation on a quantity of three carloads of this material. *Muriatic* is well sustained at \$3.50 per cwt. as the average quotation, while, on the other hand, producers are finding it difficult to meet their contracts for *oxalic*, crystals, for which as high as 65c. per lb. is being asked, but owing to the small stocks on hand it is difficult to determine whether this is an actual sale price or a nominal quotation. It is reported that there is a considerable supply of *anhydrous ammonia* in Philadelphia, but owing to the scarcity of cylinders the producers have been unable to make deliveries. This material is being offered, to those who can furnish cylinders, at 35@45c. per lb. for prompt shipment. The present scarcity of *barium chloride*, brought about by two causes, first the switching of many users from *blanc fixe* to this item during the war and secondly the destruction of the plant belonging to the largest factor in this market, has placed it in a nominal position. There is no immediate relief in sight and \$150@\$180 per ton will continue as the listing for some time. The *formaldehyde* situation seems to be somewhat easier and although production is nowhere near normal, because of the short supplies of *alcohol*, nevertheless an offering of a 50-bbl. lot at 52c. was heard during the week.

Coal-Tar Products

This market is reported on the decline, but as yet no evidence in price changes can be observed. Now that the break is supposed to have occurred, buyers are anxiously waiting to see how far prices will drop. The export business is in as bad condition as it has ever been previously, the war excepted, and with Japan not only out of the buying position but offering resale material below the domestic market, the present waiting position of the buyer seems to be justified. Against this, however, there is the shortage of crude materials and poor transportation facilities to weigh before definitely deciding a big slump is due. *Alpha naphthylamine* dropped to 55@60c., against 65@70c. of the previous week, but even at the new level there has been very little activity. With the principal producer completely sold up on *naphthalene*, there is very little material to be had of any grade except in small resale lots, which are commanding 17@18c. for *flake* and 16@17c. for *balls*. *Paradichlorbenzol* came down slightly and is now listed at \$1.50@\$1.55 per lb., against \$1.65 previously quoted.

Waxes

Interest in this market continues to center on the *paraffine* grades, which have come up throughout the list. No contracts for large quantities are being placed and the prices quoted are those prevailing on the small resale lots which are jumping around the trade.

Miscellaneous Materials

Barytes, quoted f.o.b. Kings Creek, advanced approximately \$2 a ton on both the ground white and off-color product, moving upward from \$20@\$22 and \$16@\$18 respectively as per last week's quotation to \$22@\$25 and \$18@\$20. *Feldspar*, ground, in car lots, f.o.b. Baltimore, showed an advance from \$18 to \$22 per gross ton.

Inquiries for *graphite*, especially the 90 per cent grade of flake, at prices ranging from 8½c. to 9c. per lb., f.o.b. Ashland, Ala., continue strong. It is reported that during the week a shipment of one 60,000-lb. car of 85 per cent guaranteed *carbon*, Alabama flake, was shipped at 11c. delivered. Accumulated stocks are being cleaned up rapidly through the heavy demand for both the lubricating and the 90 per cent crucible grades, and indications are that prices will show a rise if the domestic material continues in use.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots		Less Carlots	
Acetic anhydride	lb.			$0 65	$0 75
Acetone	lb.	$0 15	$0 20	.21	.22

Sodium silicate, solution (60 deg.)	lb.	.03¼	.03	.04 –	.05
Sodium sulphate, crystals (Glauber's salt)	cwt.	1 60	1.70	1 75	2 50
Sodiumsulphide, crystal, 60–62per centcone	lb.	.09 –	.10	.10½	.11
Sodium sulphite, crystals	lb.	.03½–		.04 –	.06
Strontium nitrate, powdered	lb.	.17½–	.18½	.19 –	.20
Sulphur chloride	lb.	.05½–		.06 –	
Sulphur, crude	ton	22.00 –			
Sulphur dioxide, liquid, cylinders	lb.	.09 –		.10 –	.12
Sulphur (sublimed), flour	100 lb.	3 35 –		3.40 –	3.65
Sulphur, roll (brimstone)	100 lb.	3 20 –		3.30 –	3.40
Tin bichloride (stannous)	lb.	.42½–		.46 –	.50
Tin oxide	lb.	.60 –	.63	.65 –	
Zinc carbonate, precipitate	lb.	.16	.18	.19 –	.20
Zinc chloride, gran.	lb.	.13	.13½	.13½–	.17
Zinc cyanide	lb.	.49		.50 –	.60
Zinc dust	lb.	.12½		.13 –	.15
Zinc oxide, U. S. P.	lb.	.18 –	.19	.20 –	.21
Zinc sulphate	lb.	.03½–	.03¾	.04 –	.06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities.

Alpha naphthol, crude	lb.	$1.40 —	$1.50
Alpha naphthol, refined	lb.	1 60 —	1 70
Alpha naphthylamine	lb.	.55 —	.60
Aniline oil, drums extra	lb.	.35 —	.40
Aniline salts	lb.	.40 —	.50
Anthracene, 80% in drums (100 lb.)	lb.	.90 —	1 00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.35 —	1.40
Benzidine, sulphate	lb.	1 15 —	1 25
Benzoic acid, U.S.P.	lb.	.90 —	1.00
Benzoate of soda, U.S.P.	lb.	.80 —	.90
Benzol, pure, water-white, in drums (100 lb.)	gal	.27 —	.40
Benzol, 90%, in drums (100 lb.)	gal	.25 —	31
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate (nominal)	lb.	3 50 —	4.00
Beta naphthol, sublimed (nominal)	lb.	80 —	.90
Beta naphthol, tech (nominal)	lb.	65 —	85
Beta naphthylamine, sublimed	lb.	2.25 —	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	18 —	19
Ortho-cresol, in drums (100 lb.)	lb	23 —	25
Cresylic acid, 97-99%, straw color, in drums	gal	1 10 —	1 20
Cresylic acid, 95-97%, dark, in drums	gal	1.00 —	1 05
Cresylic acid, 50%, first quality, drums	gal	65 —	75
Dichlorbenzol	lb.	08 —	10
Diethylaniline	lb.	1 50 —	1 60
Dimethylaniline	lb.	1.35 —	1 55
Dinitrobenzol	lb.	.30 —	.37
Dinitroclorbenzol	lb	30 —	35
Dinitronaphthaline	lb.	45 —	55
Dinitrophenol	lb.	40 —	45
Dinitrotoluol	lb.	40 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal	38 —	40
Diphenylamine (nominal)	lb.	80 —	85
H-acid (nominal)	lb.	2 25 —	2 50
Metaphenylenediamine	lb.	1 15 —	1 30
Monochlorbenzol	lb.	18 —	20
Monoethylaniline	lb.	2.00 —	2 40
Naphthaline crushed, in bbls. (250 lb.)	lb.	17 —	
Naphthaline, flake	lb.	17 —	18
Naphthaline, balls	lb.	16 —	18
Naphthionic acid, crude	lb.	75 —	85
Nitrobenzol	lb.	14 —	15
Nitro-naphthaline	lb.	40 —	50
Nitro-toluol	lb.	18 —	25
Ortho-amidophenol	lb.	3 25 —	4 25
Ortho-dichlor-benzol	lb.	15 —	20
Ortho-nitro-phenol	lb	80 —	1 25
Ortho-nitro-toluol	lb.	25 —	40
Ortho-toluidine	lb.	35 —	45
Para-amidophenol, base	lb.	2 50 —	3 00
Para-amidophenol, HCl	lb.	2.50 —	3 00
Para-dichlor-benzol	lb	08 —	12
Paranitraniline	lb.	1 50 —	1 55
Para-nitro-toluol	lb.	1 35 —	1 50
Paraphenylenediamine	lb.	2 60 —	3 00
Paratoluidine	lb.	2 00 —	2 50
Phthalic anhydride	lb.	65 —	75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	12 —	20
Pyridin	gal.	2 00 —	3 50
Resorcin, technical	lb.	4 25 —	4 50
Resorcin, pure	lb	6 25 —	6.75

Salicylic acid, tech., in bbls. (110 lb.)	lb.	$0 50	—	$0.52
Salicylic acid, U. S. P.	lb.	.50	—	.60
Silol	lb.	.90	—	1 00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25	—	.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.28	—	.32
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal	.28	—	...
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal	.35	—	...
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb	$0 36	—	$0 39
Beeswax, refined, light	lb.	39	—	40
Beeswax, white pure	lb.	63	—	68
Carnauba, No. 1. (nominal)	lb.	1 00	—	1 05
Carnauba, No. 2, regular (nominal)	lb.	85	—	.88
Carnauba, No. 3, North Country (nominal)	lb.	.43	—	44
Japan	lb	.21	—	22
Montan, crude	lb.	23	—	25
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09	—	.09½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.09½	—	10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11½	—	.12¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.14½	—	.15
Paraffine waxes, refined, 133-135 m.p.	lb.	.16½	—	.17
Paraffine waxes, refined, 135-137 m.p.	lb.	.17½	—	.18½
Stearic acid, single pressed	lb.	.25	—	.26
Stearic acid, double pressed	lb	.26	—	.27
Stearic acid, triple pressed	lb.	.27	—	.28

NOTE—Quotations on paraffine waxes are nominal

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1 80
Pine oil, pure, dest. dist.	gal	1 60
Pine tar oil, ref., sp. gr. 1.025-1.035	gal	48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal	35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal	85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal	36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1 75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots

Rosin B-D, bbl.	280 lb.	$17 50	—	$18 00
Rosin E-I	280 lb.	18 50	—	19 75
Rosin K-N	280 lb.	20 00	—	21 00
Rosin W. G.-W. W.	280 lb.	21 25	—	23 00
Wood rosin, bbl	280 lb	17 00	—	17 00
Spirits of turpentine	gal	1 85	—	
Wood turpentine, steam dist.	gal.	1 70	—	1 80
Wood turpentine, dest. dist.	gal.	1 40	—	1 50
Pine tar pitch, bbl.	200 lb		—	8 50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	15 00
Retort tar, bbl.	500 lb.	15.00	—	15.50
Rosin oil, first run	gal.	87	—	.89
Rosin oil, second run	gal.	89	—	.92
Rosin oil, third run	gal.	1 04	—	1 05
Rosin oil, fourth run	gal.	1 12	—	1.12

Solvents

74-76 deg., steel bbls. (85 lb.)	gal.	$0.40
70-72 deg., steel bbls. (85 lb.)	gal.	.38
68-70 deg., steel bbls. (85 lb.)	gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.29

Crude Rubber

Para—Upriver fine	lb.	$0.37½	—	$0.38
Upriver coarse	lb.	.28½	—	.29½
Upriver caucho ball	lb.	.30	—	.30½
Plantation—First latex crepe	lb.	.38	—	.39
Ribbed smoked sheets	lb.	.38½	—	.39
Brown crepe, thin, clean	lb.	.37	—	.38
Amber crepe No. 1	lb.	.....	—	.40

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.18½	—	$0.20
Castor oil, AA, in bbls.	lb.	.20	—	.22
China wood oil, in bbls.	lb.	.22½	—	.23½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.17½	—	.18½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.18½	—	.19½
Corn oil, crude, in bbls.	lb.	.17½	—	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.16½	—	.16¾
Cottonseed oil, summer yellow	lb.	19	—	.19½
Cottonseed oil, winter yellow	lb.	21	—	22
Linseed oil, raw, car lots, domestic	gal.	1 57	—	1 67
Linseed oil, raw, tank cars (domestic)	gal.	1 52	—	1 62
Linseed oil, boiled, car lots (domestic)	gal.	1.60	—	1.70
Olive oil, commercial	gal.	3 10	—	3 25
Palm, Lagos	lb.	.12	—	.13½
Palm, bright red	lb.	.13	—	.13½
Palm, Niger	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	13	—	.15
Peanut oil, refined, in bbls.	lb	.22	—	.24
Rapeseed oil, refined, in bbls.	gal	1.70	—	1 72
Rapeseed oil, blown, in bbls.	gal	1.80	—	1.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.17	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.12½	—	.13½

FISH

Winter pressed Menhaden	gal	$1 17	—	$1 18
Yellow bleached Menhaden	gal.	1.20	—	1 22
White bleached Menhaden	gal.	1.23	—	1 24
Blown Menhaden	gal.	1.30	—	1.32

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

STEGE—The Stauffer Chemical Co. is building a modern sulphuric acid plant here. The plant will have a daily capacity of 10 tons of concentrated acid. Estimated cost, $1,000,000.

Colorado

JOHNSTOWN—The Great Western Sugar Co., Sugar Bldg., Denver, has purchased a site here and is having plans prepared for the construction of a factory on same. Estimated cost, $2,000,000.

Connecticut

NEW LONDON—The United States Electric Co., 108 State St., has awarded the contract for the construction of a 75x101-ft. foundry for the manufacture of electric riveter and heater, at 21 Trumbull St., to A. T. Jackson & Co., 108 State St. Estimated cost, $50,000.

Idaho

JEROME—The Bd. of Trustees for the Independent School Dist. 33, will soon award the contract for the construction of a high school. Chemical and physical laboratories will be installed in same. Oliver Hill, clk.

Illinois

ASHLAND—School Dist. 212 has awarded the contract for the construction of a 1-story, 105x180-ft. high school, to C. H. Schenk, 2068 South 5th St., Springfield, at $110,000. Experimental laboratory equipment will be installed in same.

MONTICELLO—The Bd. Educ. is having plans prepared for the construction of a 2-story, 110x192-ft. high school here. A small chemical laboratory will be installed in same. Estimated cost, $200,000. J. C. Llewellyn, 38 South Dearborn St., Chicago, archt.

WAGGONER—The Community High School Bd. plans to construct a high school here. A small chemical laboratory will be installed in same. Estimated cost, $60,000. J. N. Coleman, 6257 St. Laurence St., Chicago, archt.

Indiana

SHELBYVILLE—The stockholders of the Citizens Gas Co. have voted in favor of the construction of an artificial gas plant here.

Iowa

DES MOINES—The Des Moines Fdry. & Machine Co., 314 Flynn Bldg., has awarded the contract for the construction of a 1-story, 130x220-ft. foundry and machine shop on 16th St. and Wabash Ave., to F. D. Chase, Inc., 17 Battery Pl., New York City. Estimated cost, $350,000.

Kansas

NORTON—The city has awarded the contract for the construction of an addition to the sewage treatment plant, powerhouse, dam, etc., to Green & Rickey.

Kentucky

STURGIS—The Bd. Educ. has awarded the contract for the construction of a high school here, to J. N. Boston & Son, Marion, Ky. A chemical laboratory will be installed in same. Estimated cost, $45,000.

Maine

BIDDEFORD—The Saco-Lowell Shop, 77 Franklin St., Boston, has awarded the contract for the construction of a 1-story, 160x200-ft. foundry, to the Aberthaw Constr. Co., 27 School St., Boston, at $250,000.

Maryland

BALTIMORE—The LaMotte Chemical Products Co., 13 West Saratoga St., plans to construct two 1-story laboratories. The company is in the market for earthenware, filters, crystallization vats, vacuum pumps, laboratory and general equipment. F. J. LaMotte, pres. and mgr.

BALTIMORE—The Prest-O-Lite Co., Inc., 30 East 42nd St., New York City, will soon award the contract for a 1-story, 25x50-ft. acetylene plant in connection with the 8 proposed acetylene buildings here. Estimated cost, $75,000.

FREDERICK—The Frederick County School Comrs. have awarded the contract for the construction of a 2-story high school addition, to L. C. Culler, Knights of Pythias Bldg. Plans include a chemical laboratory, machine shop, etc.

SPARROW'S POINT (Baltimore P. O.)—The Bethlehem Steel Corp. plans to increase its unit here. New blast furnaces will be installed and the capacity of the present tin plate plant will be doubled by the addition of 24 mills. Eugene G. Grace, pres.

Massachusetts

GARDNER—The Amer. Fibre Corp. has awarded the contract for the construction of a 1-story fiber manufacturing plant on Coleman St., to N. E. Frissul, at $75,000.

Michigan

BAY CITY—The Wildman Rubber Co., Book Bldg., Detroit, is having plans prepared for the construction of a 1- and 3-story rubber manufacturing building. Estimated cost, $2,000,000. Osborn Eng. Co., 2848 Prospect Ave., Cleveland, O., archt. and engr.

GRAND RAPIDS—The Oliver Machinery Co., 1025 Coldbrook St., N. E., will build a 1-story foundry addition on Coldbrook St. Foundry equipment will be installed in same. Estimated cost, $50,000. Work will be done by day labor.

New Jersey

NEWARK—Max Hertz, 68 Oliver St., has awarded the contract for the construction of a 1-story factory addition for the manufacture of leather at 74 Oliver St., to J. W. Ferguson Co., United Bank Bldg., Paterson. Estimated cost, $20,000.

TRENTON—The Bergeuman Rubber Corp., East State St., is in the market for $60,000 worth of machinery for plant now being constructed. Herbert Coleman, pres.

TRENTON—The John E. Thropp Sons Co., Fair St., has awarded the contract for the construction of a 1-story, 150x160-ft. foundry on Fair St., to the Austin Co., Bulletin Bldg., Philadelphia, Pa. Estimated cost, $36,000.

New York

BROOKLYN—Henry Holder, archt. and engr., 242 Franklin Ave., plans to construct a 1-story, 100x250-ft. foundry. Estimated cost, $250,000. Owner's name withheld.

BUFFALO—The Jacob Dold Packing Co., 745 William St., had plans prepared for the construction of a tank house and a fertilizer building. Estimated cost, $250,000.

TONAWANDA—The Bd. of Pub. Works has commissioned Chester & Fleming, consult. engrs., Union Bank Bldg., Pittsburgh, Pa., to make a report on the sewerage and sewage disposal systems for the city.

Ohio

RAVENNA—The Natl. Furnace Stove Co. is having plans prepared for the construction of a 1-story, 80x220-ft. office and foundry building. Estimated cost, $125,000. M. Minsman, mgr. D. C. Smith, 4500 Euclid Ave., Cleveland, archt. and engr.

Pennsylvania

BLAIRSVILLE—The Western State Hospital for the Insane plans to construct a sewage disposal plant, concrete hospital buildings, etc. at Torrance, near here.

PHILADELPHIA—The Keystone Leather Co., 9th and Westmoreland sts., plans to build a 1-story, 45x50-ft. factory addition on 19th and Ontario Sts. Estimated cost, $10,000.

WILKES BARRE—The Wilkes-Barre Berlois Tin Co., Pennsylvania Ave., plans to build a 2-story, 75x75-ft. tin factory. Estimated cost, $40,000.

South Carolina

CAYCE—The Seminole Fertilizer & Oil Co., Jacksonville, Florida, has purchased site here and had plans prepared for the construction of a fertilizer and mixing plant here. Noted May 12.

Texas

ALPINE—E. F. Berkeley, mayor will soon award the contract for furnishing material and labor including a sedimentation tank, etc., for the construction of a sewer system for the city.

Virginia

MARTINSVILLE—S. G. Whittle, Jr. will receive bids until July 15 for the construction of a 2-story high school here. A chemical laboratory will be installed in same. W. C. Northup, Winston-Salem, N. C., archt.

RICHMOND—The Gould Fire Prevention Products Co., 215 Travelers Bldg., is in the market for full equipment for manufacturing oil, lead and zinc paints.

Washington

VALLEY—The Amer. Mining Production Co. is building a kiln, etc., for the treatment of magnesite. Estimated cost, $50,000. Howard F. Wierum, engr.

Wisconsin

APPLETON—St. Elizabeth Hospital plans to build a 4-story hospital. A chemical laboratory will be installed in same. Estimated cost, $500,000. Address Franciscan Sisters.

BEAVER DAM—The F. Kassman Mfg. Co. plans to build a 1-story, 60x120-ft. molding foundry addition on Main St.

CORNELL—The Cornell Wood Products Co. has awarded the contract for the construction of a 2-story, 44x320-ft. paper making plant here, to W. E. Uhle, Stevens Point. Estimated cost, $1,000,000.

PORT WASHINGTON—The Turner Mfg. Co. is having plans prepared for the construction of a 1-story foundry here. Estimated cost, $50,000. F. D. Chase, Inc., 645 North Michigan Ave., Chicago, engr.

RACINE—S. C. Johnson & Son, 1012 Sixteenth St., rejected bids for the construction of a 4-story, 60x160-ft. warehouse and varnish plant. Work will be readvertised. Noted June 9.

WAUKESHA—F. C. Blair & Son, 240 B'way, plans to build a 1-story foundry.

Wyoming

SHOSHONI—The Wyoming Chemical Products Co., Duluth, Minn., plans to build a plant including several buildings for the manufacture of alum and epsom salts from the natural deposits near Shoshone Siding along the Chicago, Burlington & Quincy R.R. Estimated cost, $200,000. The company is in the market for 3 triple effect evaporators, drying equipment, etc. W. G. Wey, engr.

Ontario

BRANTFORD—S. C. Johnson & Son, Racine, Wis., is having plans prepared for the construction of a factory to manufacture floor waxes, varnishes, etc.

TORONTO—The Bd. Educ., College St., plans to construct a 3-story technical school including chemical laboratory equipment, etc. Estimated cost, $400,000. Address Dr. McKay, Central Technical School, College St.

TORONTO—The Canada Creosoting Co., 1006 Canadian Pacific R.R. Bldg., plans to construct a plant and is in the market for creosoting cylinders etc. Estimated cost, $150,000.

Quebec

MONTREAL—The Natl. Drug Co., St. Laurence St., will soon receive bids for the construction of a plant in the St. Henry Dist. Estimated cost, $275,000.

MONTREAL — The Phillips Electrical Co., Craig St., West, has awarded the contract for the construction of a 2-story, 40x60-ft. factory for the manufacture of electrical goods, on Henri Julien St., to Nicholson Co., St. Catharine St., West, at $22,000.

ST. ANNE DE MONTS—The Great Eastern Pulp & Paper Co., London, Great Britain, plans to build a pulp and paper plant here.

SHAWINIGAN FALLS—The Northern Aluminum Co. will soon receive bids for the construction of an office building and is in the market for laboratory equipment.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its twelfth semi-annual meeting as follows: June 28 and 29 will be spent in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE FOREST PRODUCTS LABORATORY will hold its decennial celebration at Madison, Wis., July 22 and 23, 1920.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INSECTICIDE AND DISINFECTANT MANUFACTURERS' ASSOCIATION will hold its mid-summer meeting at Boston, July 15 and 16.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE ILLINOIS MINING INSTITUTE will meet in Chicago, June 23 to 26.

THE STEEL BARREL MANUFACTURERS' ASSOCIATION will meet in Chicago, June 24.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Industrial Notes

THE ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., announces that George P. Mills, formerly electrical sales engineer of the General Electric Co., Philadelphia, has joined the staff, to take charge of and specially develop electrical industrial heating furnaces.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING Co. at the annual meeting of stockholders, held at East Pittsburgh, Pa., June 9, re-elected the following directors for three years: Guy E. Tripp, chairman of the board of directors of the Westinghouse Electric & Manufacturing Co., New York City; Joseph Marsh, president of the Standard Underground Cable Co., Pittsburgh, Pa.; H. H. Westinghouse, chairman of the board, Westinghouse Air Brake Co., New York City; Albert H. Wiggin, chairman of the board of the Chase National Bank of New York. George W. Davison, president of the Central Union Trust Co. of New York City, who was selected by the board of directors to succeed James N. Wallace, deceased, was elected by the stockholders for the term expiring June, 1921. The election was decided by the largest number of votes (personal or proxy) ever cast in the history of the company. This company also announces that G. B. Rosenblatt, who specializes in the commercial and technical activities in the West with respect to metal mining and smelting, coal mining and oil, and electrometallurgical and electrochemical industries, has moved his headquarters from the Salt Lake City office to the San Francisco office.

HAMILTON & HANSELL, INC., of New York City, has moved its offices to 15-21 Park Row, New York City. N. V. Hansell is president, H. A. DeFries vice-president, and J. Herlenius treasurer-secretary.

THE CHEMICAL CONSTRUCTION Co., New York City, has moved its New York office from 30 East 42nd St. to 51 East 42nd St.

THE MERRILL Co., San Francisco, Cal., announces that it is now prepared to deliver standard sizes of the Merco Nordstrom Plug Valve from the plant of the Swenson Evaporator Co. at Angola, Ind., which is now manufacturing these products for the Merrill Co. Inquiries regarding the valve and orders for the valve can be handled by the Chicago office, and Eastern consumers will save considerable in freight as well as in time of delivery, if orders are placed there.

THE RESEARCH CORP., New York City, has just opened up an office in Chicago at 76 West Monroe St. H. M. Pier, at present commercial representative, will be Chicago district representative.

WILLIAM C. REDFIELD, formerly Secretary of Commerce of the United States and now president of the American-Russian Chamber of Commerce, spoke before the civic industrial committee, Chicago, recently on business conditions in Russia.

THE INDUSTRIAL TRACK CONSTRUCTION Co. of St. Louis has established a branch office in Memphis, Tenn., headquarters in the Randolph Bldg. This company specializes on industrial track layouts. H. A. Nims is general manager.

THE LAKEWOOD ENGINEERING Co., Cleveland, O., has established branch offices in the Central Bank Bldg., at Memphis, Tenn. C. F. McArdle will be in charge of the territory.

S. F. BOWZER & Co., INC., of Fort Wayne, Ind., has appointed A. B. Carriger district manager, Falls Bldg., Memphis, Tenn.

WILLIAM D. EDWARDS, of Chicago, has established a consulting engineering office at 116 South Front St., Memphis, Tenn. The mechanical features of industrial drying and dehydrating plants in the fertilizer business and allied industries will be dealt with.

THE LOWE BROS Co., paint and varnish manufacturer of Dayton, Ohio, has established a branch sales office at Shelby and Nettleton Sts., Memphis, Tenn.

DR. OTTO K. ZWINGENBERGER has moved his offices from 13 Park Row to 38 Park Row, New York City.

THE INTERNATIONAL OXYGEN Co., of Newark, N. J., announces that Eugene Schoen, general manager, has sailed for Europe to make an inspection of the company's branches in London and Paris, and to extend the business of the company in France, England, Belgium, Germany, Switzerland, Sweden and Denmark, where reconstruction following the war has stimulated the demand for oxygen and hydrogen-generating apparatus.

THE BUR-MAC CORP., 1 Liberty St., New York, has been organized as a dealer in industrial chemicals, particularly used in textile, paper, tanning, soap and chemical manufacturing. Swen Ringborg is president, M. E. McGovern vice-president, and W. R. Burrows treasurer.

THE MERRILL Co. has retained the services of W. H. Campbell as auditor of the Chicago office. Mr. Campbell was recently connected with the Government food administration.

THE AMERICAN BLUE PRINT PAPER Co., 455 Plymouth Court, Chicago, has developed the Baker process for making duplicate waterproof tracings. The lines of the Baker prints are photographed on chemically prepared surfaces — tracing cloth, paper or other pliable material. The duplicate tracings are covered with waterproofing and the lines are actually produced in the waterproof coating. Corrections on the duplicates are made quickly because the lines erase very easily. This process is very convenient where a full drawing would necessarily have to be retraced on account of changing just a small portion or detail. A duplicate Baker print can be made having any desired portion left out, after which the change in details can be inserted, thus producing a new tracing with minimum cost.

THE WESTERN FOUNDRY Co., Chicago, has purchased a 3-acre plant at the corner of Wentworth Ave. and 16th St., Chicago Heights, to be used as an addition to its manufacturing operations.

THE ILLINOIS TOOL Co. of Chicago has secured a new building at the northwest corner of Erie and St. Claire Sts., for use as a general sales room, office and manufacturing plant to produce a large variety of tools.

THE WATERBURY Co. of New York, manufacturer and dealer in wire and manilla rope, has opened a Chicago branch at 609 North LaSalle St.

THE LAMBERTSON JAPANNING WORKS will occupy a 1-story building at 4010 North Claremont Ave., Chicago.

THE COLOMBIAN COMMERCIAL CORP., LTD., Earl Harding, president, 54 Dey St., New York City, has been organized to develop trade with Colombia from an international viewpoint. It offers its services to manufacturers of North America in developing a market for merchandise in Colombia and importing raw materials therefrom. Manufacturers interested in this country can secure a complimentary copy of the *Colombian Review* on application to the corporation.

THE AFFILIATION of Westinghouse, Church, Kerr & Co. and Dwight P. Robinson & Co., Inc., which was announced some time ago, is to be known until the completion of the merger as the Westinghouse, Church, Kerr & Co., Inc. Offices have been moved from 37 Wall St. to 125 East 46th St., New York City.

THE EASTON CAR & CONSTRUCTION Co. has removed its general offices from 30 Church St. to larger quarters in 50 Church St., New York City.

THE AMERICAN METALLURGICAL CORP., Philadelphia, announces the closing of a contract with the Thermoid Rubber Co., Trenton, N. J., for the installation of electric oven equipment to take care of the production of a special processed product to be placed on the market by this company. The installation involves a number of new principles specially pertaining to solvent recovery and automatic control of heat temperatures.

THE E. I. DU PONT DE NEMOURS POWDER Co. has declared the regular quarterly dividend of 1¾ per cent on the common and 1¾ per cent on the preferred stock, payable Aug. 2 to stock of record July 20.

E. I. DU PONT DE NEMOURS & Co. declared quarterly dividends of 4½ per cent on the common, payable $2 in cash and $2.50 in common stock and 1¾ per cent on debenture. Common is payable June 15 to stock of record of May 29 and debenture July 20 to stock of record July 10.

THE U. S. INDUSTRIAL ALCOHOL Co. has declared a dividend of $2 a share for the second quarter of the year 1920 on the common capital stock of the company, payable June 15, 1920, to stockholders of record June 1, 1920.

THE UNION CARBIDE & CARBON CORP. has declared a quarterly dividend of $1.50 payable July 1 to stock of record June 10. Previously it paid $1.25 quarterly.

THE CENTRAL LEATHER Co. has declared a regular quarterly dividend of 1¾ per cent on the preferred stock, payable July 1 to stock of record June 10.

Index to the Current Volume

FOLLOWING the custom established by this journal beginning with vol. 1, there is bound in this issue the current index. A special effort has been made to produce an index that would be exceptionally useful. It has not been compiled in a hasty or careless manner, but according to a well-defined plan worked out by the editorial staff, with a special view to the reader's interests.

It seems appropriate at this time to say a word in regard to the proposed 20-volume index to CHEMICAL & METALLURGICAL ENGINEERING regarding which we circularized our subscribers last fall. The response was so favorable that we planned to prepare the index, but have been deterred in so doing on account of the shortage of paper and the greatly increased mechanical cost of production. These conditions were not foreseen when the index was proposed, but they necessitate abandoning the project for the time being.

A Question of Professional Ethics

CODES of ethics have been drawn from time to time and proposed for adoption by various bodies of professional men. In their essence such codes must be broad and general, leaving to the individual the nicety of interpretation in particular cases. When the test comes we discover not so much the efficiency or deficiency of the code as the integrity of the man; and after all that is the crux of the whole matter whether we have codes or not. Of course codes are helpful even to men of good intentions, just as padlocks are discouraging to those of evil design, and it is just as well for men of high ideals to formulate a statement of what they believe to be good conduct for themselves and others. So we have no quarrel with codes, though we admire ethical conduct the more where no code is written.

A recent case in point is the action of THEODORE J. HOOVER in offering to submit in evidence in the flotation litigation between Minerals Separation, Ltd., and the Miami Copper Co. a document which came into his possession when he was general manager of Minerals Separation in 1907. The document in question is a copy of "The Theory of Concentration Processes Involving Surface Tension," by HENRY L. SULMAN and HUGH F. K. PICARD, consulting metallurgists to Minerals Separation then and now. When written, it purported to be a full and complete treatise on the subject, embodying the authors' ideas on the science and technology of the flotation process, and it is the same document to which we referred in our issue of March 3, 1920, when we commented on the discrepancy between the ideas held by Minerals Separation in 1907 and those advanced by Mr. SULMAN in his gold-medal paper before the Institution of Mining and Metallurgy in 1920. The document was given by Mr. SULMAN to Mr. HOOVER in 1907, and subsequently remained in his possession for more than twelve years without request for its return. In the meantime Mr. HOOVER severed his connection with Minerals Separation and has not been in its employ since 1910.

Such was the status when in 1919 Mr. HOOVER had occasion to delve into the record of the case of Minerals Separation, Ltd. vs. Miami Copper Co. From his affidavit on the subject we learn that as a consequence of his investigation he was convinced "that the present contentions of the complainant therein as to the scope of United States Patent No. 835,120 are so entirely opposed to the statement of two of the patentees as contained in the treatise, above referred to, as to amount, in my opinion, to an attempt to perpetrate a fraud on the court and to impose an unwarranted and unjustifiable burden upon the mining industry of the country."

With regard to the state of the art prior to the date of application for Patent No. 835,120, Mr. HOOVER says that the ideas of SULMAN and PICARD as given in the treatise are "wholly inconsistent with the position for which their assignee, Minerals Separation, Ltd., is now contending in this case."

With this as a background, we may ponder the delicate position in which Mr. HOOVER found himself. As a former employee, at one time under contract with Minerals Separation, he legitimately came into possession of documentary evidence of the avowed opinions of that company's metallurgists as to the scientific basis of the flotation process. Twelve years later, as a private engineer and professor of mining and metallurgy in Stanford University, he finds his former employers engaged in litigation, basing their contentions as to the prior state of the art on statements wholly inconsistent with those given in the treatise mentioned. What was Mr. HOOVER to do? Had he any duty at all in the matter? If so, what was it and to whom? Was his possession of the treatise a matter of confidence which he was bound to keep inviolate? Had he any obligation to Minerals Separation under his former contract of employment? Was it his duty to speak or keep silent on the subject?

We can imagine the soul-searching effort to find the proper answer to these and other questions, because the decision when made would be fraught with important consequences. If Mr. HOOVER remained silent and allowed Minerals Separation ultimately "to perpetrate a fraud on the court and to impose an unwarranted and unjustifiable burden upon the mining industry of the country," he might be considered accessory before the fact. On the other hand if he opposed the claims of

his former employers they might brand him as treacherous and disloyal, and seek to discredit him in various ways. The path of duty finally led Mr. HOOVER to an exposure of the facts as set forth in his affidavit. But the determining motive to which we want to direct attention is that he was moved to break silence, as he testifies, "particularly as I believe that the rights of the public are also involved."

Evidently Mr. HOOVER'S sense of duty to the public transcended all other considerations, and few will question the soundness of his decision. For ourselves we are glad to see so important a question resolved as a matter of ethics free from technicality.

Just a Little Strike

ON THE 18th of this month the switchmen and yard employees of the railways in Baltimore expressed by a strike their impatience over what they regarded as dilatoriness on the part of the authorities charged with the problem of finding a satisfactory readjustment of their wage scale; that is, a scale that the railways could meet on the one hand, and which would be acceptable to them on the other. The strike, as some labor leaders are constantly telling us, is their only weapon and their only means of expression. Since neither sword nor gun nor any other weapon is necessary to register impatience, the present walk-out must be regarded as an expression of opinion rather than as a blow, so far as its intent is concerned. The gentlemen were annoyed and this is the way in which they tell it. At present writing the strike has extended through the Philadelphia district and reached Jersey City.

Now let us see what this expression of opinion costs. Baltimore is headquarters for the manufacture of tin cans in the Eastern district. The factories are there. The corn and tomato crops of Delaware, Maryland and New Jersey are ripening. There is no reserve tin plate in existence. It cannot be made unless the steel is transported into the works and the cans transported away to the canneries. Nevertheless the crops are ripening, and no cans are being made or delivered in this region. Therefore most of the corn and tomato crop in the states mentioned will have to rot if the strike continues. There's no market for this immense amount of perishable goods now. They are needed for our winter food supply. Of course it may be said that tomatoes are 90 per cent water, and that we can get water from the pump, but tomatoes contain vitamines and they make other foods edible which otherwise are not. Canned corn and tomatoes are necessaries.

There's an immense crop of sweet corn in Maine, and this also is chiefly dependent upon Baltimore cans. A few cans may come in from Rochester, N. Y., if the strike does not extend out there, but only a small fraction of those needed. And a very few may be drawn from Portland, but not enough to count. The farmers—poor Rubes!—didn't know the yardman mind or the switchman conscience. They planted up to the limit, and now the joke is on them. Then next winter the joke will be on us. There is some danger, however, that the great American sense of humor will fail us all by the time cold weather comes around.

Out in Newcastle, Pa., there are two tin-plate mills and a Carnegie steel plant. They were shut down from April 10 to June 7 for lack of coal. And the plate mills couldn't get steel; all because of transportation difficulties due to strikes. These strikes also were expressions of opinion. The immediate result was that five to six thousand men were thrown out of work. They have sold their Liberty bonds, used credit to the limit at the groceries, and are in arrears for rent. It takes a lot to support a family for two months at present prices. Now the mills have started up and the men are working, but the situation is delicate. Freight moves very slowly and at any fresh disturbance they must close down again.

The connection between steel mills and tin-plate mills and can factories and canneries is a kind of frayed-out shoestring. Transportation is needed and there is hardly any transportation of freight. It is too late now to make up all the cans needed. In Indiana there are 5,500 acres planted in tomatoes that face nearly a total loss. Wisconsin has 60,000 acres planted in peas. The seed cost $9 a bushel and it takes three and one-half bushels to the acre. That means an investment of nearly $2,000,000 by Wisconsin farmers for seed alone. If they are able to can half the crop owing to some early deliveries of cans, they will be lucky. The rest is in the lap of fate as may be determined by the meditations and opinions of the railroad employees.

Sardines are beginning to run along the Maine coast, but there are no cans at hand. And there's no use in catching them if they can't be packed. Fish do not keep well if exposed to the air.

In other words, the gentlemen engaged in switching cars are annoyed. They register their annoyance by their "only weapon," the strike, and this in turn causes the rich products of our blessed land to rot in the fields, it bankrupts farmers, and dooms hundreds of thousands of our people to hunger and millions to distress. If any king of the past two hundred years were to have inflicted such a punishment as a mark of his disapproval he would have been dethroned. People will not stand that sort of thing from kings. But we seem to endure it with complacency from yardmen and switch-tenders. Perhaps their hearts bleed for the suffering in prospect.

The Stable Market For Chilean Nitrate

VARIOUS sources of information, notable among which are the United States Department of Agriculture and the Chilean Nitrate Committee, show that the demand for Chilean saltpeter in the world market has been the criterion of the nitrogen requirements for explosives and fertilizers for a number of years past. This is not an amazing fact when we consider that the industry dates back to the discovery of caliche by the early Indian tribes of Tarapaca, that sodium nitrate was known in the time of PHILIP V and that actual production of saltpeter began in Huantajaya during the early part of the eighteenth century. Tradition has it that when the Indians revealed their discovery to the priest he announced that the explosive soil was not the abode of an evil spirit but a gift of Providence for increasing the productiveness of the earth. Thus it was simultaneously found to be both an explosive and a fertilizer.

Wise, in truth, are the present-day dealers in this old-established commodity who philosophically accept the advent of new processes for securing nitrogen compounds. In spite of the upheaval of the market due to

the war the business is even now showing signs of future stability. The development of better methods for supplying the wants of mankind should always be welcomed if for no other reason than the consequent addition to individual wealth.

Experience with the marked industrial improvements of the past hundred years has taught us that such processes of growth are more often evolutionary than revolutionary. This is easily accounted for in that economic laws essentially function to keep pace with the new achievements and with small disturbance to industrial welfare. Nitrogen-fixation plants will supply the consumer with new compounds of nitrogen, but the demand is growing at such a rate as to still require an increasing output of the product from the deserts of Chile.

The most fundamental change which will likely take place in the Chilean nitrate industry is the forced application of modern methods to mining and leaching operations. Competition which necessitates improvements over aboriginal processes is wholesome indeed.

Organizing the Steel Workers

FAR from the failure of the iron and steel strike of last autumn having settled the matter of whether or not the iron and steel industry should be "organized," the present situation is that there is competition in the matter of endeavoring to do the job. The work of organizing that led to the recent strike was conducted more or less under the auspices of the American Federation of Labor. There is an organization about forty years old, called the Amalgamated Association, for several years "affiliated" with the Federation, which aspires to do all the organizing there is to be done in the industry, and wanted the Federation to leave the matter to it, but the Federation at the annual convention in Montreal turned down the proposition and laid plans for a fresh campaign of its own. The old committee, which survived after the Fitzpatrick and Foster resignations, following the failure of the strike, is to be disbanded and an entirely new committee formed, profiting by the mistakes the last time.

The Amalgamated Association has been losing ground more or less continuously, except during the late war, since its Homestead strike of 1892, and of late has controlled practically nothing except 30 or 40 per cent of the hot-mill labor at the sheet and tin-plate mills, the tin-house labor at the same tin-plate mills, and most of the iron mills from Pittsburgh west. One advantage it had to offer to those signing its scales was that the matter was over for a year, and the management had to deal with a mill committee instead of with individuals. The scale agreement prevented a strike as long as its terms were complied with. Last fall the Amalgamated Association was commended for keeping its men at work, under its signed scales. Instead of being encouraged to continue the system the Amalgamated Association proposed to the sheet and tin-plate manufacturers hitherto signing the scale that for the new year, beginning July 1, the men for whom the scale was signed should have the right to go on strike if the Amalgamated Association should at any time organize other departments operated by the company signing the scale, and the scale then presented should not be accepted by the management. Under Amalgamated Association rules ten men can form a union and get a charter. Thus the hot-mill men could get the picklers in, then the hot-mill men plus the picklers could get the cold-rollers in, then the hot-mill men plus the picklers plus cold-rollers could get the annealers in, and so on. The Republic Iron & Steel Co. bought a ten-mill sheet plant last year for the hot-mill labor of which the Amalgamated Association scale has hitherto been signed. According to the plan proposed, this could be used as a lever gradually to get the company's plate mills, pipe mills, bessemer converters, open-hearth furnaces and blast furnaces into the union class, bit by bit, otherwise down would go the Deforest sheet mills.

Needless to say the proposal was rejected and the scale conference adjourned, leaving it that the Amalgamated Association will after June 30 make all the trouble it can. So will the American Federation of Labor, and the two organizations will not work together, the point being that the officials of each organization wish to retain their positions. This may represent a new form of competition, but it is no new thing for labor organizations to compete with each other, as witness innumerable cases of construction jobs being held up because there was a plurality of unions desirous of doing the same piece of work.

Nothing has been said thus far as to what either organization wants for the men it is desired to unionize. That may be announced later if the leaders have the necessary leisure. The fact is baldly apparent that the main thing is to "organize" for the sake of organizing.

Something— But Not Enough

THE Sterling-Lehlbach bill, which provides for the retirement of Government employees, has just become effective, and those in the service above 62, 65 or 70 years of age, according to the branch of the service, are to be retired on a pay which is pitifully small, especially for those who have occupied responsible positions. After thirty years of service, retirement is on the basis of 60 per cent of the salary, but a maximum of $720 per year limits the retirement pay. Those who have been fifteen years in the service retire on a 30 per cent basis, but here again the maximum retirement pay is limited to $360 per year.

It is certainly gratifying to know that Congress has at last recognized the principle of retirement provision for superannuated civilian employees. However, it is not pleasant to consider the situation of a technical expert who has been in the service for thirty years and who under the new law is required to surrender 2½ per cent of his basic salary, being provided with the munificent reward of $60 per month when he retires for old age. The professional men of the country cannot look with satisfaction upon such an arrangement.

It is up to us, therefore, to get busy and see that a more nearly adequate arrangement is made for the retirement of specialists. Particularly for those in technical and other professional lines the retirement should be upon a basis comparable with the dignity of the position which they have occupied. This is only one of the efforts which is essential in order to restore the Federal services to that position of self-respect and reliability which can reasonably be demanded if proper care is taken of the individuals' interests, both during and after public service.

Readers' Views and Comments

Putrefaction and Decomposition

To the Editor of Chemical & Metallurgical Engineering

SIR:—Dr. George L. Hagadore of Chicago has contributed an illuminating article to *The Undertakers Journal* on Putrefaction and Decomposition, which is so replete with chemical and biological news that I offer some notes taken from it as a worthy supplement to Prof. Moadinger's masterly contribution to corpse chemistry which I abstracted and which you were good enough to print some time ago.*

"Decomposition," says Dr. Hagadore, "is the separation of the component principles of the body, which are organic, nitrogenic or proteid compounds . . . . The separation takes place by chemical analysis under conditions causing fermentation." Of cells he says that "like all organic structures they have a limited period of life, their continued decay and death necessitating reproduction, which takes place in higher animal life by fission." "Blood," he continues, "is another unstable tissue," and he says it is the first tissue of the body to decompose.

"The body has fifteen chemical elements, all of which are combined in characteristic proportions (by the law of chemism) to form compounds, the proximate principles of which are about one hundred, which are divided into four classes, viz., inorganic, organic, non-nitrogenized, organic-nitrogenized and the principle of waste. Chemical elements, with the exception of the gaseous oxygen O_{16}, hydrogen H_1, and nitrogen N_{14}, do not exist alone in the body, but form compounds. The proximate principles O_{16}, H_1 and N_{14} are gases possessing great atomic heat, while C_{12} has the greatest atomic cohesion. O_{16} will combine with all the elements except fluorine, FO_8." The function of O_{16} "appears to be the oxidation of albuminous, oleaginous and saccharine compounds to their ultimate forms of urea, carbonic acid, etc."

Later on the author states that "according to the Law of Chemism, atoms are not satisfied to remain in complex compounds, readily giving up the unsatisfied atoms from molecules in the compound, which is termed analysis, or chemical decomposition of the body."

The sequelæ of decay are described in rather minute detail and the phenomena are explained by the statement that "the gases that chemists and pathologists describe are purely new chemical compounds caused by the chemicals in the body readily giving up the unsatisfied atoms in the molecules and the atoms combining with the O_{16} gas, the H_1 gas and the N_{14} gas."

Here we have a remarkable example of the reach of technology beyond the advancement of pure science. Let us consider a few of the high lights of Dr. Hagadore's great research. We are told, for instance, that decomposition takes place by chemical analysis; that blood is a tissue, and of proximate principles, which will be a new concept to most of your readers, I believe. The reproduction of life in the *higher* animals by fission is a new biological idea. The principles of waste to some minds will probably involve C_2H_5OH, but the inert H_1 molecule will probably strike most readers as a novelty. It is not surprising, however, that such a super-ozone as O_{16} will oxidize the oleaginous and saccharine compounds of the body, whether it be dead or alive.

MARTIN SEYT.

Air Furnace vs. Cupola Semi-Steel

To the Editor of Chemical & Metallurigcal Engineering

SIR:—I have recently had occasion to refer to my remarks at the A.I.M.E. meeting, Feb. 16 to 19, New York City, reported on page 391 of the March 3 issue of CHEMICAL & METALLURGICAL ENGINEERING, as follows:

"Attention was called to the exceptional wearing qualities of some semi-steels by R. F. Harrington, who thought that real information was needed as to whether cupola or air-furnace semi-steel was superior for abrasion-resistant parts such as locomotive cross-head shoes. Mechanics generally prefer cupola semi-steel, even if physical tests appear quite similar. For determining this essentially practical point, a good testing machine should be designed."

The writer appreciates fully the difficulty often encountered in reporting absolutely correctly the statements of different speakers on such occasions. It does seem, however, in this particular case that some of my remarks were entirely contrary to the statements reported as above, as can be seen from the extracts from a copy of stenographic notes submitted by the Secretary of the A.I.M.E. for my record:

"This so-called semi-steel . . . has always been of rather great interest to the speaker from the standpoint of its wear-resisting properties. We hear a great deal about the high tensile strength, transverse load and the increased deflection that is obtained through the use of steel, as compared to metal which has been made without the use of steel. This is particularly true in the case of the frictional parts of the locomotive, where much material of both kinds as mentioned above is used. . . . I have often wondered how the wear-resisting qualities of these two metals would compare, viz., metal made through the use of steel and one through the use of the open-hearth or air furnace type of melting unit. . . . In the railroad world . . . are many able men who believe that the addition of steel materially reduces the wearing quality of a metal as compared to a metal of the same analysis obtained through the reduction of carbon by other means. I believe that . . . some endeavor ought to be made to test out the relative wear-resisting qualities . . ."

Boston, Mass. R. F. HARRINGTON.

Increased Production of Sugar in Belgium

The Belgian production of sugar, which in 1918 was 70,000 tons and in 1919 113,000 tons, will easily reach 160,000 tons this year and will cover the interior needs of Belgium without obliging it to have recourse to foreign stocks. If the production attains 200,000 tons, as it did several years ago, there is a possibility of a surplus for export.

American Society for Testing Materials

Review of the Technical Papers Presented Before the Meeting at Asbury Park, N. J., June 22 to 25, Especially Relating to Molybdenum Steel, Transverse Fissures in Rails and to Testing Machines

EDITORIAL CORRESPONDENCE

AMERICAN Society for Testing Materials held its twenty-third annual meeting at Asbury Park, June 22-25, 1920, which was quite well attended by men interested in different substances together comprising engineering materials either from a producer's or a consumer's standpoint. As formerly, the main activities were confined to committee meetings, only the finished result of which was exhibited in open meetings. Nearly a hundred changes or additions were made to the standard and tentative specifications, most of them being matters of detail.

One action almost promised a year ago, was left undone—the restoration of phosphorus and sulphur limits in steel. Many 1918 specifications were raised 0.01 per cent to admit the necessary war tonnage—half of them replaced last year on materials of special purity or composition, and the remaining specifications (comprising the largest part of the tonnage) left with high limits for twelve months more. Now comes the time to replace the lower limits, but the committee finds that the conditions existing a year ago still remain, consequently consideration will again be deferred for a year. No question was raised as to the possibility of "conditions"—principally high-sulphur coal—ever being better, lacking an insistent spur; meanwhile a joint committee[1] has embarked upon a pretentious investigation as to the effect of sulphur and phosphorus on tonnage steels. Before scientific results can be obtained from this investigation—if they ever are obtained acceptable to both producers and consumers—the psychological factor may have intervened, and the purchaser become so satisfied with higher sulphur and phosphorus shapes that he wonders at his former insistent demand for the lower limits. "Anyway, if the steel mills cannot produce the stuff you want, . . .?"

CORROSION OF SHEET METAL

Another important committee report was on the present condition of a great number of 16- and 22-gage corrugated sheets exposed to atmospheric conditions for several years. Three different sets were exposed, one at Annapolis, where deterioration has proved slow; at Fort Sheridan, where the conditions are more severe, and at Pittsburgh, where the sheets are failing badly. The May, 1920, inspection of the 41-months' old sheets at Pittsburgh showed that out of 146 sheets of copper-bearing steel and iron (including puddled and ingot iron, open-hearth and bessemer steel) all with copper content above 0.15 per cent, ranging from 0.18 to 0.62, forty-two have failed, or 28 per cent. Out of eighty-four non-copper-bearing sheets, containing copper less than 0.15, ranging down to 0.01 per cent, eighty-one have failed, or 97 per cent. Atmospheric conditions at Pittsburgh and Fort Sheridan therefore appear to be resisted better by corrugated sheets containing appreciable amounts of copper. Coupons reserved from all these exposed sheets will now be exposed in salt, mine, and tap water, to check the result of the atmospheric-exposure results. Exposure of galvanized and other protected sheets probably cannot be undertaken on account of the difficulty in guaranteeing unchanged location for the long term of years which would be required.

SHATTERED ZONES IN RAILS

In discussing James E. Howard's paper "On the Shattered Zones in Certain Steel Rails, With Notes on the Interior Origin of Transverse Fissures," M. H. Wickhorst reviewed the gradual increase in our knowledge regarding simple transverse fissures. As these failures appeared (they were first described by Mr. Howard in 1911) the rails containing them were studied from many angles. Chemical analysis gave no clue to the trouble. Microscopically, the rails appeared all right. Tension tests cut from transversely-fissured rails gave consistent results in flange, web, or outside of head, yet the same tests from the interior of the head showed low ductility.

Transverse fissures, properly so called, were always characterized by a flat break, square across the rail. All these breaks showed a "detail fracture" consisting of a roughly oval area giving a bright silvery appearance, at the center of which was a granular spot—the so-called nucleus, apparently the point of initial growth. Suspicion that the interior of the rail head and base contained shattered metal became a certainty with Waring and Hofammann's[2] discovery of "worm holes"—deep gouges produced by the action of hot HCl on polished sections. Rawdon and Epstein[3] very elegantly proved that such deep-etching marks represented in fact pre-existing cracks in the metal, a conclusion which has been substantiated by other investigators in their efforts to locate them prior to acid treatment.

Literally thousands of minute fissures exist in the deep seated interiors of heavy, hard rails, unaccompanied by non-metallic inclusions, and following both the grain boundaries and crystalline cleavages. Rawdon believes intracrystalline directions predominate.) Howard, however, shows that they do not extend closer than $\frac{1}{2}$ to $\frac{5}{8}$ in. to the hot-sawed ends of the rail, so that the shattered zones are entirely surrounded by sound metal, a circumstance which leads both Howard and Wickhorst to ascribe their origin to a time subsequent to hot-sawing. Another possibility—not mentioned at the meeting—appears worthy of discussion, and that is that pre-existing cracks might be cured in cooling surface regions exposed by the saw. Doubtless the mechanical working effects caused by hot-sawing are not comparable to the rolling stresses induced below the lateral

surface. Summation of this evidence, together with collateral experiments on internal stresses in rails and steel tires, convinces Howard that such defects in the shattered zone are cooling or shrinkage cracks.

Relation Between Shattered Metal and Transverse Fissures

All agree that transverse-fissured rails should be avoided, but lacking definite information as to their nature and cause, not much progress can be expected toward their systematic elimination. Deep etching cracks seemed the first real clue. While Robert Job agreed with Howard that no connection has yet been established between shattered zones and transverse fissures, G. F. Comstock takes rather sharp issue with them and contends that at least one transverse crack may reasonably be assumed to pre-exist at the nucleus of a transverse fissure, even though none are found elsewhere in the piece.

In different stages of development transverse fissures are found in all sizes of rails. Among 663 fissures occurring on one railroad, 535 occurred on the gage side of the head, 128 over the web, and none on the outside of the head. Transverse fissures have been found 1½ in. from the end of a rail, a location where internal strains were certainly the dominant ones. Well advanced transverse fissures have been found barely an inch apart, a development which could not take place as a result of bending stresses, even though one is inclined to disagree with the author that the most recent track measurements show fiber stresses inadequate to account for the rupture of rails by bending alone. Howard's suggestion that shattered interiors may even suppress fissuring in service by allowing the diffusion and therefore relief of internal strains transmitted from the cold-rolled running surface is questioned by Rawdon, who said, "It would seem logical to infer that if several *incipient* transverse fissures form in close proximity to each other, the 'diffusive action' referred to should be sufficient to prevent further development so that *well-developed* transverse fissures ought never to occur in close proximity to one another." On the other hand, a sound rail possessing moderate ductility should be safer against internal fissuring; unfortunately modern traffic conditions need a strong rail, to withstand the track loads, and a hard rail, to prevent undue distortion —a combination in carbon steels which unfortunately demands large cross-section, high carbon and low ductility. Apparently traffic conditions and "margin of safety" in carbon rails are an almost impossible combination of requirements.

Molybdenum Steels

G. W. Sargent presented an interesting paper giving the results of experience with molybdenum as an alloying element, dating back to 1899. At that time he, as well as several other investigators, was handicapped by the fact that the alloying elements available were quite variable in quality. Saladin[4], Guillet[5] and Cohade[6] have described the properties of a number of molybdenum steels made at Creusot, which researches showed high Mo steels to possess a special constituent which makes the steels brittle and hard, and even develop transverse weakness.

Swinden[7] prepared several low-molybdenum quaternary alloys showing high strength and good ductility, resembling nickel and chromium : nickel steels. Adoption by the consumers has been slow, however, owing to the comparatively high cost of molybdenum and the uncertainty in quantity and quality of the supply. Investigations within the last few years show the metal to be comparatively wide-spread and plentiful, and at present ample producing capacity is available for any expected demand. Electric-furnace ferromolybdenum and chemically prepared calcium molybdate may also be obtained in quantity.

Manufacture

Sargent says that molybdenum alloys present no difficulties in any modern steel-making process. Calcium molybdate is not to be used in the crucible process, and in general, low-molybdenum ferros are to be preferred on account of their lower melting point and ready diffusion. A typical basic open-hearth heat from a campaign producing about 6,000 tons is cited showing a charge at 10 a.m. of 99,100 lb. clean scrap, 30,100 lb. cold pig and 73,100 hot metal, with some spiegel iron, nickel scrap and nickel metal. Additions in order are as follows: Carbon, three of limestone, four or ore totaling 11,000 lb., nickel, and four of ferro-silicon, this last at 11.16 p.m. Then quickly followed 1,000 lb. 16 per cent spiegel; 1,504 lb. 50 per cent ferromolybdenum, 3,150 lb. 66 per cent ferrochrome, and 1,500 lb. ferromanganese, and the heat, tapped at 11.56 p.m., teemed into 20 x 24 ingots with a recovery of 93 per cent. Analyses follow:

	Carbon	Mn	Cr	Mo	Si
Preliminary from laboratory.....	0.15	0.24	....	.....	....
Added.....	0.19	0.61	1.02	0.347	....
Total....	0.34	0.85	1.02	0.347	....
Final.....	0.30	0.64	0.77	0.350	0.12
Wanted,	0.25 to 0.35	0.50 to 0.80	0.80 to 1.00	0.25 to 0.50	0.25

Yields for several heats averaged: Ingots, 87 per cent of melting; billets, 80 per cent; bars, 94.4 per cent of billets; total yield, 66 per cent of metal charged into furnace. Analyses from two 40-in. corrugated ingots made at the Bethlehem Steel Co. showed no excessive segregation of any element.

The author presented several diagrams similar to Fig. 1 comparing the physical properties of popular alloy steels with and without ½ to ¾ per cent Mo. Annealing these oil-quenched steels at progressively higher temperatures decreases the ultimate strength and elastic limit—which, by the way, are quite close together, and increases the reduction in area and elongation. These diagrams show consistently a high reduction in area with a relatively low elongation. Quenching from as high as 2,000 deg. F. does not impair the physical properties nor cause the grain growth characteristic of overheated steel.

Physical Properties

Structurally, a quenched steel low in molybdenum (C 0.32, Cr 0.90, Mo 0.40) is martensitic. Drawing at 900 to 1,000 deg. F. reverts this into fine short pearlite filaments, and at 1,400 deg. F. the ferrite colesces into rounded masses, when the steel is well annealed and machines easily. A higher molybdenum steel (C 0.39, Cr 1.05, V 0.17, Mo 0.87) is finely pearlitic on oil quenching from 1,600 deg. F., and remains unchanged until drawn at 1,400 deg. F., upon exceeding which it is annealed. Swinden's researches indicate that molyb-

denum enters and toughens ferrite as solid solution when no Cr nor an excess of Mn is present. Otherwise it forms double carbides in addition, imparting additional hardness and strength. Thermal studies indicate that beyond 800 deg. C. (1,475 deg. F.) some compound is found in the austenite which upon cooling first dissociates at normal Ar, with precipitation of Fe_3C, later breaking up into a Mo:Fe compound at about 500 deg. C. (930 deg. F.), which further dissociates, giving a Mo:Fe solid solution only upon repeated reheatings. Hence the flatness of the physical properties vs. annealing temperature curves, and the persistence of the fine pearlitic microstructure.

Replying to questions, Mr. Sargent said that one of his torsion tests on low-molybdenum steels gave thirteen twists in an eighteen-in. length before breaking. Testing billets transversely to the direction of rolling gave no more evidence of transverse weakness than disclosed in carbon steels. Molybdenum added to gray cast iron in the ladle up to 4 per cent increased its tensile strength from 32,500 to 38,400, with a concomitant increase in Brinell hardness of 235 to 311. The graphite flakes were notably straighter edged and sharper. These results were substantiated by similar ones on semi-steel.

Non-Ferrous Alloys

Sub-Committee IX reported progress in its effort to systematize in some manner the names of ferro-alloys. Some idea of their task may be had from a glance at the list of usable alloys, twelve pages in length, among which there are perhaps 500 alloys known by name. How descriptive or apropos are these names may be inferred from the common "German-silver," neither German nor silver, or the designation of commercial aluminum mixtures by number (there are two No. 31's on the market at present). The committee recommends "nickelene" for Ni: Zn: Cu alloys, perhaps a doubtful improvement. However, no small advance would be made if a Zn: Cu alloy would always be some kind of a brass and not a "bronze" in order to denote some superexcellence imparted by a small percentage of a third element. A like committee of the British Institute of Metals believes that systematic names should have preference. The American committee recommends that commercial names which have become established by long usage, such as brass, bronze and cupro-nickel should be retained, differentiating by color, preferably. Thus a Zn 40 per cent Cu 60 per cent would be called a yellow-red brass. If it contained some tin it would be a tin yellow-red brass. Systematically the latter would be a tin-zinc-copper alloy, the first metal representing the smallest proportion, which must have at least 1 per cent present to be worthy of mention.

Effect of Tin on Brasses

William Campbell presented "A Note on the Constitution of Certain Tin-Bearing Brasses," in which he clearly explained the rather puzzling fact that a relatively slight variation in tin often causes the most profound physical changes in the alloys. Microscopically, some naval brass castings were found to resemble Muntz metal, in that they consisted of a mixture of alpha and beta constituents; some of them appeared like bronzes (alpha and eutectoid), while a third class consisted of alpha, beta and eutectoid. All of them were cast to the following specifications: Cu 60 to 65 per cent, Sn 0.5 to 1.5 per cent, iron 0.5 per cent maximum, Pb 1.0 per cent maximum, Al 0.5 per cent, Zn remainder.

He therefore studied the region of the ternary diagram shown in Fig. 2, both as cast and after annealing for two hours at 650 deg. C., and furnace cooled, finding results very similar to those of Hudson and Jones.* The alpha-beta-eutectoid complex is found in an approximately rectangular area, from which it is immediately

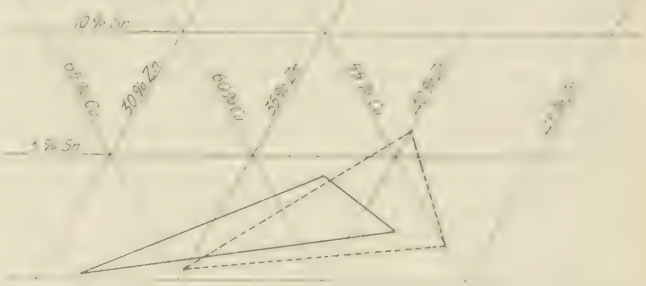

FIG. 2. PART OF Sn : Zn : Cu : TERNARY DIAGRAM, SHOWING STRUCTURE ANALOGOUS TO GUN METAL

seen that as the copper content of the cast alloy increases from 56.5 per cent, the amount of tin which will cause the alloy to change from the ductile "naval brass" type to the less desirable "gunmetal" type decreases from 2 per cent to less than 0.5 per cent with 67 per cent of copper. Consequently in proportioning such alloys it should always be clearly understood that the amount of tin should be inversely proportional to the copper. Corresponding facts for the annealed state are shown by the dotted triangle in the figure.

Testing Machines

A number of papers describing testing machines of various kinds were read, one attracting the most attention being perhaps that by A. S. Cushman on "A New Method of Testing Galvanized Coatings." This is merely a portable device for measuring the amount of hydrogen evolved when dissolving a given area of coating in concentrated HCl. A short length of 2½-in. tubing, properly convoluted on its bottom edge to fit the shape to be tested, is puttied down on the desired spot, closed with a stopper, connected to a gas burette and the entire system filled with water. Then by means of proper

*Journal, Institute of Metals, vol. 14, p. 98

thistle tube, an undetermined quantity of HCl -$SbCl_3$ solution is introduced into the test ring, the evolving hydrogen being collected in the burette. Action is very rapid for about 30 seconds, slowing down to almost zero as the bare iron is exposed. The system is again washed out with water to insure all the hydrogen entering the burette, the volume noted, and by using a proper factor, the coating calculated in any units desired.

Hiding Power of Paints

"An Instrument for Measuring the Hiding Power of Paints" was described by R. L. Hallett. It consists merely of a long microscopic tube with plane ground glass for objective and small hole for ocular. If under this ground glass is placed a card having a contrasting stripe painted across it, the line of demarcation becomes more and more indistinct as the objective is withdrawn; finally a distance is reached where by diffusion the field appears uniformly illuminated. This vertical distance is measured and is found to be proportional to the contrast existing on the card under view.

The ground glass was prepared by polishing back an overground piece until a white card with a black stripe would become merged under view at an objective distance of about 15 cm. Calibration is required for each instrument, and is done by viewing various grays, ranging from best white to darkest obtainable black, each tone having previously been analyzed for white and black by a Howland color photometer. In this way a logarithmic curve was established, using objective distance as ordinate and per cent of hiding power as abscissa.

This instrument evidently can be used for any spreading rate, and for any color over any background. Its chief difference from the cryptometer[10] is that the latter measures 100 per cent hiding in liquid paint, while the new device measures to within 5 per cent any percentage of hiding less than 100 in a dried coat applied to any desired surface at any desired rate.

Colorimeter for White Paints

A. H. Pfund notes that heretofore it has been extremely difficult to evaluate various so-called white paints because their departure from white is so very slight, and in developing a "New Colorimeter for White Pigments" makes use of optical principles for intensifying these differences to measurable quantities. He defines a white surface as one which reflects white light non-selectively. While truly white light is as difficult of attainment as a truly white pigment, for practical purposes so-called white pigments may be compared by comparing the way they reflect blue, green and red light. If a certain paint reflects the three equally well, it is white; if blue is reflected less completely, the paint is not white, but reflects selectively, and in this case has a yellow tint—a condition common to all commercial "white" pigments. Sublimed magnesium oxide has a reflecting power of 87 per cent (the standard of brightness) and is practically white. Lithopone in glycerine, however, reflects red 77 per cent, green 75 per cent and blue 71 per cent. It evidently is not so bright as MgO, and in comparison will also appear yellow-tinted. On the other hand, Titanox reflects red 77 per cent, green 71 per cent and blue 64 per cent. It is even less bright than lithopone, and appears yellow to MgO, yet lithopone appears bluish when alongside.

[10]Journal of the Franklin Institute, Nov., 1919.

Such numerical results define each paint uniquely, and make purchasing independent of standard samples. The instrument is reproducible at any point and dependent only upon physical constants. It is evidently useful in studying aging phenomena, the relation between hiding power and brightness, the effect of minute additions of colored pigments, and so on.

Briefly, the instrument intensifies selective reflection by multiple reflection of diffused electric light between parallel surfaces covered with the paint in question. Emerging beams are compared with the source by an ordinary photometer cube, viewed through screens of colored glass or solutions and a brightness match established and measured.

Plastometer

An improved plastometer which should be applicable to the investigation of many problems connected with paints, clays, greases, lards, soaps, lubricants and the like was described by Henry Green. As described a year ago in the *Proceedings*, the material under study is forced through a long capillary by air pressure, the rate of flow then being plotted against the pressure, or, more preferably, against the shear so induced. Rate of flow is measured by measuring the air displaced in the receiving vessel through a very delicate gas flowmeter.

Maxwell in his "Theory of Heat" points out that if any stress, no matter how small, be applied to a true liquid, a permanent deformation ensues. Flow-shear curves for liquids plotted by the plastometer agree with theory, since they are straight lines passing through the origin, the viscosity being a function of the slope. Plastic solids, on the other hand, require a certain definite unit force before flow (or deformation) occurs. Graphically, this means that the flow-shear curve should cut the X axis at a definite value ("yield value") equal to the shear required for incipient movement. Actually, at low pressures the curves for paint pastes (for instance) bend so as to approach the origin, apparently acting like viscous liquids at low pressures and as plastic solids at higher.

Microscopical observation of such capillary movement shows that at rest the vehicle wets the walls of the tube, the pigment touching the walls at but very few points and existing as interlocking floccules of relatively large mass. Slight pressure causes this interlocked mass to move *en bloc* so that shear is confined to the truly liquid vehicle. As the pressure increases, however, the pigment deflocculates, and movement is "telescopic," *i.e.*, the inner portions move much faster than the outer ones —true "fluid" motion. In this state lubrication is not complete and surplus force is required to overcome the largely increased friction between the moving particles.

From these results it appears that "plasticity" is a term of composite significance. Two substances may have the same yield value and yet one have a higher mobility (or fluidity, which is an analogous term) giving higher rates of flow for given pressures. On the other hand the mobility of a pair of substances may be the same, yet the more plastic would have the lower yield value.

True matching of plasticity is consequently a most difficult operation, involving substantial agreement of two pairs of factors, each to each, and can be successfully done only by painstaking studies by the plastometer or some instrument measuring the factors equally well.

Legal Notes

By Wellington Gustin

Egyptian Lacquer Manufacturing Co. vs. Chemical Company of America

The Egyptian Lacquer Manufacturing Co. of Rahway, N. J., instituted suit for damages against the Chemical Company of America for pollution of water furnished it by the city of Rahway. The Chemical company attacked the complaint as failing to establish a right of action. This complaint set out that the city of Rahway is authorized by law to take such portion of the water of the Rahway River as may be required to furnish the inhabitants of the city with wholesome water for domestic and other uses; that the Egyptian company has a factory in the city for the manufacture of chemical products requiring a large quantity of water which was furnished it by the city; that the Chemical Company of America, having a factory at or near the river, emptied therein refuse from its factory above the intake of the city which so polluted the water furnished by the city that the complainant was injured in its use, and business was prevented from being carried on.

Is the Complaint a Cause of Action?

In passing on the law involved to determine whether the complaint disclosed a cause of action, the Supreme Court of New Jersey said it was clear from the complaint that although the city and the Chemical company are riparian owners, the Egyptian company is not, and further that there exists no contractural relation between the complainant and the Chemical company, or between the city and the Chemical company, as to the supply of water. This, said the court, presents the question whether, granting the right of the city to maintain an action against the Chemical company because of the pollution, the Egyptian company has such right, not being a riparian owner.

This is not a case of an indictment for creating or maintaining a public nuisance, or for the violation of any statute against the pollution of a running stream, but a suit for damages resulting from a special injury based upon the non-performance of a duty which the plaintiff claims was due to it from the Chemical company, and the claim is not sustained by the complaint, as the court found.

Dismissal of the Complaint

It says: "We may assume in this case that a liability existed in favor of the city as a lower riparian owner for the pollution of the stream by a higher riparian owner; but there the obligation ceased, for the right of action would not pass to a non-riparian owner merely because the latter had contracted with the city for the furnishing of the water, for his right depends upon his contract with the city, which might provide for the very character of water which was supplied. The liability of the defendant, if any, rests upon his violation of the legal right of a lower riparian owner, unless it had contracted with the plaintiff." But there was no claim of contract between the Chemical company and either the Egyptian company or the city. And if such a contract existed between the Chemical company and the city the court was of the opinion it could not inure to the benefit of the Egyptian company, as user of the city's water. Neither did the complaint show as a matter of law that the Chemical company as a riparian owner owed any general duty to the public or a special one to the complainant. The complaint was dismissed.

Agreement to Order as Soon as "a Car or Two" Has Been Used Held Valid

The Lakeside Forge Co., of Erie, Pa., has won in the Pennsylvania Supreme Court on its judgment against the Freedom Oil Works. An action for breach of sales contract for a year's supply of fuel oil had been entered into by correspondence between the parties. Defendant agreed to furnish oil and plaintiff accepted the offer, stating that it had a "car or two" coming from another source and would commence on the order "as soon as this is used up." This was on Aug. 16.

The Forge company by letter on Nov. 15 called upon the refinery for a car of the fuel oil, and two days later received a reply, refusing to deliver it, alleging that plaintiff's delay had operated as a cancellation of the contract. As a matter of fact plaintiff had seven cars of fuel oil coming on a former contract when this contract was made and this was the oil it used from August to November. The statement that it had a car or two coming was made honestly but without investigation.

The parties had further correspondence and telephone conversations, but the refinery refused to perform the contract, and plaintiff was forced to supply its requirements for the balance of the contract year from other sources of supply, at the prevailing market price. Then the present suit was brought to recover from the defendant refinery the difference between the price paid in the open market and the contract price. The trial court gave a judgment for this difference and the refining company appealed.

"A Car or Two" an Indefinite Number

The Supreme Court found the agreement, made by the correspondence, plain and said it obligated defendant to supply plaintiff's requirements for one year, less the amount due on a prior order. Until that was exhausted plaintiff couldn't demand oil on the contract in suit; hence defendant was not released because plaintiff failed to make a premature demand. Neither regarded the amount so due as the essence of the contract or attempted to fix it definitely. Plaintiff says "a car or two," and defendant says "to begin after you have taken out what is yet due you on previous contract." The court said "a car or two" signifies an indefinite small number and may include as many as seven. It is similar to "a few." Where indefinite words are used and the naming of the quantity is regarded, not as in the nature of a warranty, but only as an estimate of the probable amount, good faith is all that is required of the party making it.

Refinery Lost on Each Gallon Furnished

In a letter to plaintiff the refinery states the real truth that each gallon furnished under the contract would be at a considerable loss to it. But the court said the refinery would not be released from all liability for a year because by a fortuitous circumstance it was saved harmless for the first two months' supply. This was to defendant's advantage. And to justify rescission of a contract because of falsehood it must have been relied on by the complaining party to his detriment.

Notice to Discontinue Manufacture Relieves Buyer From Responsibility for Full Purchase Price

The Appellate Division of the Supreme Court of New York reverses judgment in the action of Frederick T. Commoss, as seller, to recover for 220 net tons of steel plates against William C. Pearson. These plates were to be shipped to a party in California, and from there exported to Japan. After the sales contract was made the Government promulgated a rule against exporting plates to Japan after a given date. The manufacturers of this plate, the National Enameling & Stamping Co., reported it impossible to make the plates before expiration of the time limit. The buyer failed to get an extension export permit, and wrote the plaintiff to do nothing further with the order for that time. The manufacturers replied to the buyer saying the order would be held until it heard from him again. The buyer further telephoned to the office of the seller, Commoss, and, not finding him in, gave the information to one McFarland, who promised to communicate same to Commoss.

At this time none of the plates had been made up. Later the full order of 220 tons of plates was rolled; this was done without any notice whatever from the buyer, Pearson.

The law applicable to the case is found in section 145, subdivision 4, of the Personal Property Law of New York, providing:

Provisions of the New York Law

"If, while labor or expense of material amount are necessary on the part of the seller to enable him to fulfill his obligations under the contract to sell or the sale, the buyer repudiates the contract or the sale, or notifies the seller to proceed no further therewith, the buyer shall be liable to the seller for no greater damages than the seller would have suffered if he did nothing toward carrying out the contract or the sale after receiving notice of the buyer's repudiation or countermand. The profit the seller would have made if the contract or the sale had been fully performed shall be considered in estimating such damages."

Now, said the court, if the buyer seasonably notified seller's agent not to proceed with the manufacture of certain steel plates, and also notified the mill which was making the plates, and the mill promised not to proceed further without notice from the buyer, the buyer was absolved, under the above law, from damages for labor and material thereafter expended in manufacturing the plates, and was not liable for the full purchase price on breach of the sales contract.

Buyer's Counterclaim Denied

Again, the buyer set up a counterclaim because the goods were not tendered to him within the time specified in the contract, but the court said he could not complain where he had directed the suspension of their manufacture until further notice which he had never given. Neither was the contract for the sale of steel plates for export an illegal contract because thereafter a Government embargo on such shipments was promulgated, where it is not shown that either party intended to make shipment without Government permit. The parties might lawfully stipulate that the payment should become due forthwith, as was done in this case, after the plates were rolled and before delivery.

The court said that undoubtedly all parties believed that the embargo upon the exportation of these plates would soon be released, and they acted accordingly; but neither the mill nor the seller had the right to proceed, after having been notified to suspend the manufacture until further notice from the buyer. If that further notice were delayed an unreasonable length of time, it would amount to an absolute repudiation; but when the mill acquiesced in the request to suspend the manufacture until further notice, and when such a request, transferred to plaintiff, brought no protest, the buyer might properly rest upon its liability for such damages as had accrued upon the contract at the time the notice was given, and the seller cannot hold the defendant to any greater damages.

The Borderland of Manufacturing — When Mining Is Also Manufacturing

The Supreme Court of Pennsylvania has been called to pass upon the question whether a mining company in that state was not really carrying on the business of manufacturing. The action was one instituted by the state against the Welsh Mountain Mining & Kaolin Manufacturing Co., and arose out of a statute allowing to mining companies an exemption from capital stock tax of so much of the capital stock as is used in manufacturing. The company claimed it was engaged in manufacturing and on that ground refused to pay the capital stock tax.

The facts were that the company was incorporated under the Pennsylvania laws for the purpose of "mining fire clay, fire sand, feldspar and kaolin, with the right to prepare for market and vend the product of their mines." This company, during the tax period involved in the suit, leased its property and plant to the Silican Products Co. and the Silican Sand Co., which operated the mining property.

Basis of the Claim

The mined rock is crushed and sieved to the desired mesh. The silica sand thus obtained is used principally for molding in the steel foundry trade, and to some extent for concrete in the building trade. The rock has no commercial use or value as rock, but when changed into sand is known in the trade as "silica sand," and is worth from 45c. to 60c. a ton, and is adapted in that condition to particular uses, for which it was not adapted as rock.

Not Manufacturing, Says Court

Now, the question presented for the court to decide was whether this was manufacturing within the statute exempting the company from the tax. The company mines the silica rock and reduces it to desired sizes or to sand. It is still silica rock or stone bearing the appearance of the article as it leaves the mine, said the court, but with no regular shape or fixed size in the portions into which the rock is broken by the crusher. The pieces are sold as they come from the crusher without any attempt to remove the irregularities of the edges or make the pieces of uniform shape. This process is not manufacturing, the court held. And the fact that clay of various colors is sometimes added to the sand when colored silica is desired does not change the situation, said the court. That application of labor to an article either by hand or mechanism does not make the article necessarily a manufactured article was announced as a settled principle of law.

Factors in the Conversion of Sodium Formate to Oxalate

A Study of the Temperature, Pressure and Caustic Composition Factors Influencing the Percentage of Conversion of Sodium Formate to Oxalate—Temperature Control Essential—Oxalate Conversion Curves and Interpretation

By E. H. LESLIE* and C. D. CARPENTER†

THE formate process for the manufacture of oxalic acid as used in Europe has many variations, but basically it consists in allowing carbon monoxide gas to react upon a heated caustic alkali in the presence of more or less water, the temperature being controlled so that the formate produced is not decomposed into oxalate and carbonate. Without attempting to show the mechanism, that is, the part played by the water, the reaction may be represented:

$$NaOH + CO \rightarrow H\text{-}C\begin{matrix}O\\ \diagdown ONa\end{matrix} + x \text{ cal.}$$

Temperature Control Essential

One of the greatest difficulties in so making sodium formate is the control of the temperature. Since the formate producing reaction is exothermic, a tendency to build up the temperature locally exists, thus bringing about a decomposition of the formate which has been produced. Fortunately the temperature at which formate is decomposed is considerably higher than that at which it is formed in the process under discussion, so that with adequate means of controlling the temperature difficulty need not be encountered in working the process. The temperature at which the decomposition referred to will take place and also the manner of the decomposition is a function of the composition of the material undergoing treatment particularly as regards its content of caustic alkali.

It can readily be seen that the controlling of the amount of caustic alkali in the finished synthetic formate is no easy matter, for while at the start of the reaction period the carbon monoxide comes in contact with the caustic readily, in the later stages of the conversion when the mass is pasty or solid the unconverted sodium hydroxide is brought in contact with the CO gas only slowly and with difficulty. Since the synthetic formate may thus contain caustic alkali, it is of importance to know what the effect of the presence of sodium hydroxide is on the conversion of the formate into oxalate.

Two Staged Reactions

Two main reactions take place when a pure formate is decomposed under carefully regulated conditions:

$$2H\text{-}C\begin{matrix}O\\ \diagdown ONa\end{matrix} \rightarrow \begin{matrix}C\begin{matrix}O\\ \diagdown ONa\end{matrix}\\ C\begin{matrix}ONa\\ \diagup O\end{matrix}\end{matrix} + H_2$$

sod. oxalate

$$2H\text{-}C\begin{matrix}O\\ \diagdown ONa\end{matrix} \rightarrow C\begin{matrix}O\\ -ONa\\ \diagdown ONa\end{matrix} + H_2 + CO$$

sod. carbonate

The second of these may take place in two stages: first, the formation of oxalate, and second, the decomposition of the oxalate into carbonate and carbon monoxide. It is of course necessary in commercial practice to avoid the formation of carbonate as far as possible, since the formation of this product results in a direct loss of oxalate, and also at a later stage in the making of oxalic acid in the loss of an equivalent amount of sulphuric acid.

The relative extent to which these reactions take place depends on temperature, pressure, and on the composition of the formate converted. As mentioned above, the content of NaOH in the formate is of special importance, and may introduce a further undesirable reaction, as we shall note below.

The experimental work which we report in this paper was designed to determine the effect of these various factors on the conversion of formate into oxalate.

Conversions Under Varying Conditions

Our study of the formate conversion involved the carrying out of a series of experiments in which approximately 10 g. of pure sodium formate mixed with definite amounts of sodium hydroxide were decomposed under carefully controlled conditions of temperature and pressure.

The sodium formate used contained 98.95 per cent formate and 1.0 per cent water. The caustic soda contained 92.25 per cent NaOH, 4.23 per cent Na_2CO_3 and 3.5 per cent water.

The formate and hydroxide were weighed out into a 250-c.c. round-bottomed flask, which was fitted with a one-hole stopper and pressure tube connection to a vacuum reservoir. This reservoir consisted of two 5-gal. glass bottles which were exhausted by an oil pump. A manometer indicated the vacuum in use.

When all was in readiness the round-bottomed flask containing the charge was plunged into a bath of molten nitrates of potassium and sodium contained in a 2-liter pressed steel bucket. The bucket was well insulated, and the bath could be maintained within 1 deg. C. with ease. Temperatures were measured by means of a Tycos nitrogen-filled mercury thermometer.

The flask was shaken vigorously in order to thoroughly mix the hydroxide and formate as the latter melted and the former dissolved in it, and to make uniform the temperature in the liquid mixture of these substances. The reaction was very vigorous in those cases where an extensive conversion took place, starting in from 2 to 4 min. and being complete very shortly

*Department of Chemical Engineering, University of Michigan, Ann Arbor, Mich.

†Department of Chemical Engineering, Columbia University, New York City.

thereafter. In some cases the decomposition was so rapid as to be almost explosive. In all experiments the heating of the flask was continued so that the total time was 15 min. The temperature of the bath in no case changed more than 1 deg. C. when the flask was plunged into the bath.

The conversion results in the formation of sodium oxalate and carbonate, which are solids at the temperature of the conversion. Consequently as the reaction proceeds the mass solidifies as gas is given off. This results finally in a puffed up, porous, white mass. The evolution of gas changed the pressure on the system somewhat, but this in no case amounted to a change of more than 40 mm. of mercury.

When the 15-min. heating period was complete the flask was removed from the bath, cooled, and the contents dissolved out. The oxalate was then precipitated as calcium oxalate, collected on a filter, washed carefully, redissolved in dilute sulphuric acid, and estimated by titration against potassium permanganate which had been standardized against pure sodium oxalate.

Discussion of Experimental Errors

It is evident that certain errors are unavoidable in the method we have used. One of these concerns the transmission of heat into the melted solids which are undergoing reaction. It is well known that in a case such as we are dealing with here the main resistances to the transmission of heat lie in the liquid or gas films on the two sides of the glass and not in the glass itself. The thickness of these films and hence their resistance to the flow of heat is greatly reduced by shaking the flask. In any event the results in our experiments are comparable in so far as temperature is concerned since the factors affecting heat transmission are substantially constant throughout.

We have mentioned the error due to change in pressure as the reaction proceeds. This of course influenced the results in a certain degree, but this pressure change was nearly the same in those cases where a considerable conversion occurred, and hence was nearly a constant factor. In those cases where little change occurred the pressure remained low, and as indicated in the results recorded favored the reaction. Hence the error does not destroy the conclusions drawn from the results.

Experimental Results

It is of course obvious that in order to accurately obtain continuous curves it would be necessary to perform many more determinations than are recorded as loci of the curves given, but it is believed that the data presented indicate with a fair degree of conclusiveness the effects of varying the conditions, temperature, pressure, and per cent of sodium hydroxide.

An inspection of the curves indicates that for given temperature and pressure there is some optimum percentage of sodium hydroxide. This shows up clearly in the curves, 2-in. mercury at 260 deg. C., 14 in. at 300 deg. and atmospheric pressure at 360 deg. C. It is probable that in all those cases where nearly quantitative conversions into oxalate were obtained with 1 to 1.5 per cent NaOH, a decrease in NaOH below 1 per cent and approaching 0 per cent would have given a markedly lower conversion.

The sodium hydroxide exerts a specific influence on the conversion of formate into oxalate which for want of an exact explanation we may call a catalytic influence. In addition to this catalytic effect the sodium hydroxide exerts a second influence which results in a lowering of oxalate yield. This is probably due to chemical reaction between the formate and hydroxide, thus

$$H\text{-}C\begin{matrix}O\\ \diagdown ONa\end{matrix} + NaOH \rightarrow C\begin{matrix}O\\ -ONa\\ \diagdown ONa\end{matrix} \quad H_2$$

But it may be the result of a catalysis by the hydroxide of the reaction

$$2H\text{-}C\begin{matrix}O\\ \diagdown ONa\end{matrix} \rightarrow Na_2CO_3 + H_2 + CO$$

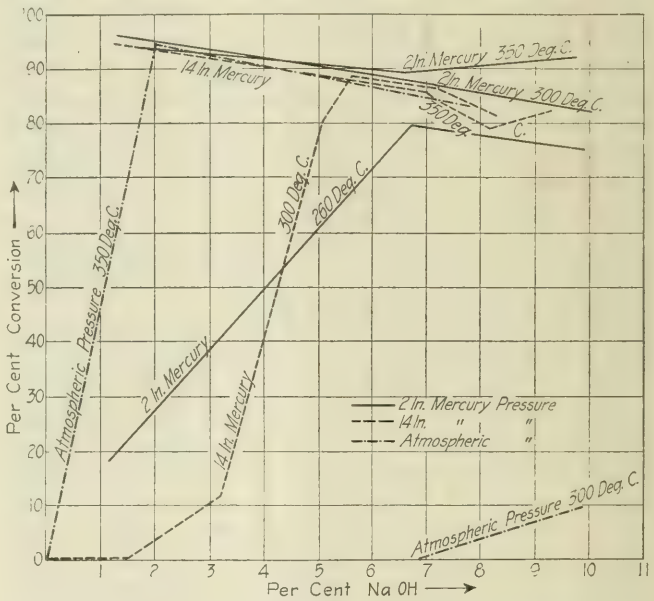
This latter reaction should probably be regarded as taking place in two steps: first, the formation of the oxalate, and second, the catalytic decomposition of the oxalate; thus

$$2H\text{-}C\begin{matrix}O\\ \diagdown ONa\end{matrix} \rightarrow Na_2C_2O_4 + H_2$$

$$Na_2C_2O_4 \rightarrow Na_2CO_3 + CO$$

Interpretation of the Curves

The point as to whether the NaOH reacts chemically with the formate, or catalyzes the carbonate forming reaction, or both, can be settled by analyzing the gases given off during the conversion and considering the



CONVERSION TO OXALATE FOR VARIABLE NaOH CONTENT AND AT DIFFERENT PRESSURES

hydrogen and carbon monoxide content of the gases in relation to the oxalate and carbonate content of the reaction product. We regret that we are unable to offer data on this point.

It is obvious from a consideration of the curves that an amount of sodium hydroxide approximating 1 per cent of the formate is the most desirable quantity to have present.

The curves show that the lower the pressure the more easily and effectively are the oxalate-producing reactions brought about. Too low pressures are undesirable from an operative standpoint both on account of cost and on account of the danger of explosion from a too rapid

reaction where fairly large quantities of formate are undergoing treatment.

In general we can say that increase in temperature produces increased yields. It is undesirable, however, to use temperatures over 360 deg. C. due to the increased rate of decomposition of the oxalate.

Considering the matter from the practical as well as the chemical standpoint, it is evident that the best conditions for the conversion of sodium formate into sodium oxalate are the following:

A proportion of NaOH approximating 1 per cent of the formate.

A pressure approximating 14 in. of mercury.

A temperature of 350 deg. C.

It is a matter of great difficulty to heat a large quantity of formate quickly to a temperature of 350 deg. C., and poor results will be obtained if the conversion takes place at lower temperatures when the pressure in use is 14 in. of mercury. The conversion process should therefore be a continuous one in which small quantities of formate only are subjected to the influence of the conditions at any one time. In this way the conversion temperature can be quickly reached, and danger of explosion which exists when large quantities are being handled is avoided. Following this general method we see no reason why results approximating a 90 per cent conversion should not be obtained in commercial practice.

Tests for Relative Corrosion

By Bertram Feuer*

Recently the researches of Bauer and Vogel,[1] Bengough and Hudson,[2] F. Goudriaan,[3] and the author with Reedy[4] have brought out some facts concerning corrosion that confirm the ideas worked out independently by various individuals using different methods of attack. In practically all these cases it was necessary to attack the problem from a more or less theoretical point of view and, no doubt, has led to promising results. Others, in their investigations, have worked for the sole purpose of seeking a remedy to counteract the deleterious action caused by the phenomena of corrosion. Among another group of workers can be classed those who have sought a means for testing or measuring the corrodibility of a metal in order to determine whether a particular metal would be best suited for a specific use. These workers have undoubtedly contributed matter of interest for the engineer who is confronted with the question from the practical standpoint and should have some means at his disposal for testing the suitability of his materials for various purposes. So far as sytematic testing is concerned, having regard to our present state of knowledge on the subject, this is out of the question.

For systematic testing it would be absolutely necessary to govern and study local conditions and other more or less accidental disturbances that occur in practice, but further difficulty is met with in sampling the metals to be tested, in reproducing the natural conditions of aëration, dilution, changes in electrolyte composition, slight mechanical abrasive actions, temperature fluctuations, etc. The oldest method is the immersion test. Strips of the metal are carefully cleaned and weighed, and are placed in samples of water or exposed to similar atmospheric conditions as will be met with in practice (e.g., in air for outdoor construction; in fumes of chemicals for metal that is to be used in industrial constructional work). After a long period of exposure the samples are taken out, carefully cleaned, dried and weighed. The loss of weight per unit surface per unit time is the corrosion factor.

In addition to the above-mentioned objections of inability to reproduce natural environments, the method possesses two great disadvantages.

1. It is very slow; accelerated corrosion tests, such as immersion in 20 per cent sulphuric acid or in 7.5 per cent sodium chloride, or again, in 1 per cent ammonium nitrate solutions, have been proposed and attempted, but it is found that the corrosion factors do not, as a rule, bear any relationship to those where the conditions of nature are at least being partly reproduced.

2. Corrosion may be either superficial or in the nature of pitting. It is obvious that a "pit" is more deleterious to strength—the important factor in constructional work—than an equivalent amount of superficial rusting. On the other hand, superficial rusting would hinder the proper action of a water meter, while a "pit" would probably cause no trouble. The process above described makes no differentiation between the two forms of corrosion. A further discord between the factors of various investigators is caused by the nature of the preliminary cleaning to which the metal surface is subjected.

G. and M. Whipple[5] introduced an electrolytic test for corrosion in which the rate of solution was accelerated by making the test piece of the metal the anode of a cell driven by current from some external source. This form of test brings out the "pittings" on the surface of the metal with great distinctness, and serves as a method for indicating the nature of corrosion.

Another electrolytic test devised by H. Hansen and W. Lewis[6] for determining the mutual corrosive effect of two metals consists in connecting electrodes of the two metals through an ammeter, keeping the solution about the electro-negative metal saturated with air, and measuring the current in the external circuit. Provided some standard metal to form the one electrode could be agreed upon, this method, which eliminates the necessity for the external current required in Whipple's test, is a great simplification of electrolytic corrosion processes.

There is one other method of testing corrodibility devised by G. and M. Whipple. This may be defined as an electrical survey method. By means of a sensitive galvanometer and a traveling contact pole of copper wire, the other terminal being connected permanently to the plate of metal, the magnitude of the current flowing through the galvanometer, when contact is made in the surface of the metal, is determined. Uniformity of surface currents is taken to indicate low corrosive tendencies, while alterations of any magnitude are associated with a tendency to rust. The value of the method seems to be somewhat vitiated by the presence of the metallic traveling touch electrode, which must undoubtedly both affect passivity and set up local currents not necessarily of constant magnitude.

The author in his work on corrosion was interested in the problem concerning water-meters and therefore

limited his study to the action of dilute solutions of the salts, commonly found in water, on brasses and bronzes. In this work a simple test with the ferroxyl indicator[7] was found useful. Later work suggested that the plotting of potential fall between the surface of the metal and the solution in which it is immersed, by the aid of an auxiliary electrode, would give figures equally significant in value and free from the disadvantage alluded to above. It should, however, be remembered that, according to theory, the rate of corrosion is determined solely by the magnitude of the local currents, and that determinations of e.m.f. are only of value in so far that they indicate solution-tendency and not the rate of rusting.

The apparatus used for this work is that ordinarily used for determination of emf. by means of a third electrode and is fully described in textbooks on theoretical electrochemistry. In this work the calomel electrode was used. For measurement of the current an ordinary instrument on which one scale division measured one milliampere was found convenient. A more sensitive current instrument was placed in the circuit in order to read current magnitudes between scale divisions of the larger instrument.

The samples tested were uniform in size, having a surface area of 20 sq.cm. Table I gives a list of the samples used together with their compositions.

TABLE I.

No.	Zn Per Cent	Cu Per Cent	Sn Per Cent	P Per Cent	Al Per Cent
1	5	95	..	..	..
2	10	90	..	..	..
3	20	80	..	..	..
4	30	70	..	..	..
5	40	60	..	..	..
6	..	92	8	..	..
7	39	60	1	..	..
8	..	95	4.5	0.5	..
9	92	..	..	..	8
10	(c. p. Zn)	..	..	..	..
11	..	(c. p. Cu)	..	..	..

The accompanying figure shows the results obtained with the ten metals. The current values are plotted as ordinates and as a matter of convenience the logarithms of the potential values were used and are plotted as abscissæ. Upon examination of the curves the relative corrodibility of the ten metals when immersed in a 0.1 normal solution of KNO_3 is evident. These results, in a sense, check with those obtained by using the ferroxyl indicator referred to above. The use of this method has proved very interesting and it is hoped that in the near future it will be possible to study other alloys together with a variety of solutions, whereby some reliable data can be obtained and possibly a satisfactory practical method of testing be devised.

Urbana, Ill.

The Lead and Zinc Industry in Japan*

LEAD is mostly found in the form of galena, which is closely associated with zinc-blende ores. The principal lead mine in Japan is the Kamioka, in Gifu Prefecture. Inquiry at the Mitsui Mining Co. (Mitsui Kozan Kabushiki Kaisha) showed that in 1918 the output of this mine was 7,408,309 lb. of lead.

The quantity and value of the annual production of lead in Japan from 1913 to 1918 is given in Table I.

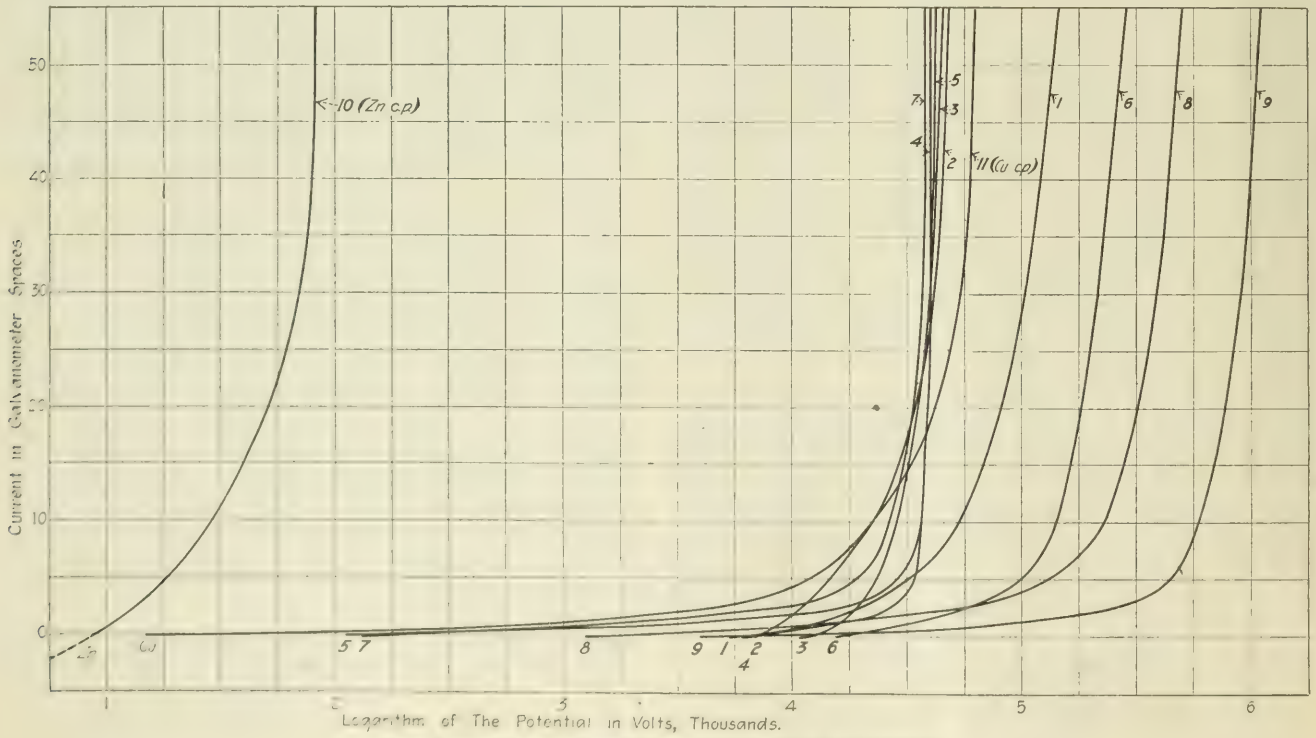
TABLE I. PRODUCTION OF LEAD IN JAPAN, 1913–1918

Years	Lb.	Value	Years	Lb.	Value
1913	8,393,138	$308,006	1916	25,268,685	$1,872,332
1914	10,138,205	412,400	1917	35,127,077	2,822,018
1915	10,567,457	486,729	1918	23,742,236	2,070,266

Okayama Prefecture leads in lead production. In 1918 the amount was given at 7,573,669 lb., valued at $675,-975. Gifu Prefecture was next with 7,440,368 lb., valued at $646,442. Other principal lead producing Prefectures, in the order named for 1918, were Fukuoka, Miyagi, Akita and Yamaguchi.

Producers and smelters were buoyed up by high prices

*Report of Vice-Consul H. T. Goodier, Yokohama, *Commerce Reports*, May 24, 1920.



RELATIVE CORRODIBILITY OF METALS TESTED

ruling during the war and by the hope that strikes and political conditions in the United States, Spain, Australia and Mexico, the principal lead-producing countries of the world, would create a world-wide shortage. However, this hope does not seem to have fully materialized, and the lead market has become quiet as a consequence. Paint manufacturers, having lost a considerable share of their trade with Singapore, the East Indies and India, as a result of renewed competition from Europe, are buying lead for actual needs only. This, together with increased cost of materials for smelting and higher wages, has caused a considerable reduction in output as compared with 1917. If the 1919 figures were available they would undoubtedly show a still more noticeable decrease in amount and value, many of the companies having been forced into financial difficulties.

Prices for lead (Australian) reached their highest in September, 1918, when 1 picul (about 133 lb.) was worth $15.52 in Yokohama. The lowest was $5.85 per picul, in June, 1914. In March, 1920, the price was $13.21, a recovery of about $4 per picul since last October. However, mounting costs make lead mining and smelting increasingly less profitable to the small company run uneconomically, as most of them are, especially in view of high transportation charges. The cost of production of refined lead is estimated at about $8 per picul at the smelters.

Imports of lead and lead ore into Japan from 1915 to 1919, largely from Australia (for lead ingots and slabs), are given in Table II.

TABLE II. IMPORTS OF LEAD AND LEAD ORE INTO JAPAN, 1915–1919

	Lead Ore		Lead Ingots and Slabs		Other	
Years	Lb.	Value	Lb.	Value	Lb.	Value
1915....	(a)	(a)	32,279,973	$1,450,656	2,872,805	$175,860
1916....	(a)	(a)	46,230,232	3,720,089	3,460,964	278,704
1917....	50,520,532	$1,253,759	35,024,068	2,926,798	1,567,652	144,154
1918....	7,989,466	191,130	120,283,002	7,351,379	1,447,808	153,538
1919....	330,667	8,007	79,607,814	5,432,046	(b)	(b)

(a) Not known. (b) Statistics not yet available.

In 1915 Australia sold to Japan 24,599,868 lb. of lead ingots and slabs, valued at $1,102,933. The same year the United States sold to Japan 5,790,156 lb., valued at $248,307. In 1919, while imports of lead slabs and ingots from Australia had increased to only 32,366,341 lb., valued at $2,551,042, imports from the United States jumped to 27,239,280 lb., valued at $1,604,866.

In 1914 Japanese consumption of lead was estimated at 43,753,000 lb., a great share of which was imported from Australia. In 1918 the estimated consumption had reached 144,025,000 lb.

Imports of White and Red Lead and Litharge

The imports of white and red lead and litharge, most of which came from the United States, are given in Table III.

TABLE III. JAPANESE IMPORTS OF WHITE AND RED LEAD AND LITHARGE

Years	Lb.	Value
1916	323,445	$31,365
1917	14,973	2,419
1918	18,401	2,661
1919	212,912	20,995

Lead is not exported from Japan in quantities sufficient to classify separately.

Only since 1913 has Japan engaged in zinc smelting. Prior to that time zinc ore was shipped abroad and the refined product then imported. The largest zinc mine is the Hikoshima in Yamaguchi Prefecture. In 1918 the production of this mine was given as 27,672,960 lb. of zinc and 230,720 lb. of lead. The estimated consumption of zinc in Japan increased from 25,512,000 lb. in 1914 to 60,761,000 lb. in 1918. Consumption has, however, very materially decreased since 1918.

Table IV shows that the production of zinc ore has been steadily declining since 1913, but that the output of refined zinc increased until 1918, in which year a decrease is shown.

TABLE IV. PRODUCTION OF ZINC ORE AND REFINED ZINC

	Zinc Ore		Refined Zinc	
Years	Metric Tons	Value	Lb.	Value
1913	34,676	$472,303	(a)	(a)
1914	14,138	140,752	13,140,265	$682,454
1915	6,121	179,845	46,958,601	6,456,866
1916	2,187	91,257	86,652,256	13,567,052
1917	163	13,576	121,596,436	13,462,153
1918	(a)	(a)	88,701,073	8,838,867

(a) Production not stated.

European Demand Stimulates Zinc Industry

When the war broke out, zinc experienced a boom in Japan, due to heavy demands from Great Britain and Russia. Prices went up, and many new companies, both mining and smelting, were formed. While there was a large disparity between costs and selling prices, these companies all made good profits. However, with the beginning of summer, 1916, prices started to go down. With decreased foreign demands and increased cost of production and transportation charges, many of these companies have had to either temporarily suspend operations or considerably restrict their activities, the latter course being taken by several of even the middle-sized companies. Much of this financial trouble noticeable among the smaller zinc operators is probably due to pyramiding subscribed capital on the basis of abnormal profits and excessive dividends declared, instead of creating and maintaining a safe reserve fund.

The estimated cost of production of refined zinc at the smelters is about $11 per picul (133⅓ lb.). Prices of 98 per cent pure zinc per picul ranged from $6.41 in June, 1914, to $27.40 in December, 1915. Since then prices have hovered around $12 as an average. In March, 1920, the price per picul was $13.96. The margin of profit, considering transportation charges, is thus proportionately low at present.

Yamaguchi Prefecture led in zinc production in 1918 with 27,672,972 lb., valued at $2,535,822. Fukuoka and Okayama followed in the order named, with over 18,000,000 lb. each. Other important producing centers were Miyagi, Hyogo, and Osaka.

Operation of Mines

In Japan, the principal uses of lead are for the making of paint, cables and piping, and in producing acetic acid. The principal uses of zinc are for plating and making paints.

In the mining of lead and zinc, primitive hand methods are used by the smaller companies. The operations of the larger ones, however, compare favorably with those used in the lead district in Idaho. There are 2,364 miners employed in zinc mining, while 1,046 are employed in lead mining.

The Mitsubishi Kogyo Kabushiki Kaisha pay their miners an average of about 75c. a day, with two holidays a month. The underground miners work about 56 hr. a week; surface workers usually have a 77-hr. week.

TABLE V. IMPORTS OF ZINC ORE, INGOTS, SLABS AND GRAINS, SHEETS AND WASTE

Year	Ore		Ingots, Slabs and Grains		Sheets		Waste	
	Lb.	Value	Lb.	Value	Lb.	Value	Lb.	Value
1915	(a)	(a)	6,487,784	$637,056	1,210,109	$157,277	11,125,057	$769,465
1916	(a)	(a)	7,218,985	980,277	1,203,998	228,577	4,401,937	427,889
1917	207,450,533	$3,899,905	10,015,693	879,392	2,694,159	595,171	1,633,445	110,124
1918	133,093,068	2,433,883	5,443,656	681,263	2,981,136	759,511	1,622,656	122,903
1919	61,845,733	1,122,932	12,629,181	1,463,480	3,276,672	555,480	722,444	36,661

(a) Not known.

The imports into Japan of zinc ore, of ingots, slabs, and grains, of sheets, and of waste during the past five years are shown in Table V.

During 1917 and 1918 a great deal of zinc ore was imported for smelting, mostly from Australia. However, since 1918 imports of zinc ore have decreased considerably, owing to a smaller foreign demand for the refined article, thus causing many smaller smelters in Japan to suspend operations.

Although no definite statistics in support thereof can be presented, indications are that foreign refined zinc and zinc manufactures, principally sheets from the United States, will once again find a growing market in Japan, owing to transhipping and speculative activities in connection with the increased demand for plating in China.

Exports and Principal Countries of Destination

The exports of zinc ore have shown a steady decline since 1915, when they amounted to 13,618,250 lb. On the other hand, exports of zinc ingots and slabs increased until 1917, since when they have shown a noticeable decrease. Japanese exports of zinc ore and of ingots and slabs from 1915 to 1919 are given in Table VI.

TABLE VI. JAPANESE EXPORTS OF ZINC ORE AND INGOTS AND SLABS

Years	Zinc Ore		Zinc Ingots and Slabs	
	Lb.	Value	Lb.	Value
1915	13,618,260	$179,846	(a)	(a)
1916	4,865,332	91,258	51,586,452	$9,596,461
1917	362,400	13,576	81,853,012	10,442,511
1918	11,332	234	37,739,584	4,519,766
1919	(a)	(a)	12,629,180	1,463,480

(a) Statistics not available.

The principal countries of destination for the exports of zinc ingots and slabs during the past three years were as follows:

TABLE VII. COUNTRIES OF DESTINATION FOR EXPORTS OF ZINC INGOTS AND SLABS

Countries	1917		1918		1919	
	Lb.	Value	Lb.	Value	Lb.	Value
Asiatic Russia	16,370,736	$1,943,703				
British India			7,851,343	$931,442		
China					2,912,616	$296,935
France	13,277,885	1,777,815	15,802,908	1,753,365		
Great Britain	42,452,701	5,472,124	9,330,916	1,166,264	8,586,588	1,048,423

1919	212,912	20,995

Water-Power Development in Canada

The Dominion Water Power Branch, Department of the Interior, and the Dominion Bureau of Statistics, Department of Trade and Commerce, have just published the results of an exhaustive census and analysis of the developed water power of Canada. Their report, with figures complete to Jan. 1, 1920, is of exceptional interest as indicative of the extent to which the water resources of the Dominion are being put to advantageous use.

Practically every great industrial center in Canada, the report declares, is now served with hydro-electrical energy and has within easy transmission distance ample reserves of water power. Active construction in hydro-electrical enterprises is fast linking up the few cities which are still unserved and which have water-power reserves in their vicinity.

Horsepower Installed

There is installed throughout Canada about 2,418,000 turbine or water-wheel horsepower, of which 2,215,000 hp. is actually and regularly employed in useful work. The larger figure includes the total installed capacity at full gate, including reserve units. It does not, however, include hydraulic exciter units. A large number of the plants now operating are designed for addition of further units as the market demands. The ultimate capacity of such plants and that of new plants now under construction total about 3,385,000 hp.

Of the total power installed 1,756,791 hp., or 72.7 per cent, is installed in central electrical stations. By central electrical stations are meant stations which are engaged in the development of electrical energy for sale and distribution. Central station power is sold for lighting, mining, the electrochemical and electrometallurgical industries, milling and general manufacturing. In the pulp and paper industry 473,265 hp. is utilized, of which 381,631 hp. is generated directly from water in paper and pulp establishments, while 91,634 hp. is purchased from hydro-central electric stations.

Other Uses of Energy—Capital Invested

Hydropower used for other purposes and other industries may be listed as follows: For lighting, 434,613 hp.; in the mining industry, 177,728 hp.; in flour and grist mills, 42,736 hp.; in lumber mills and sawmills, 37,918 hp.; in other manufacturing industries, 172,955 hp. In further reference to the foregoing total of water power developed in Canada it ought to be noted that during the fiscal year ended March 31, 1919, there were exported from plants included in the tabulation 175,000 hp.-yr.

The total installed water-wheel and turbine power in hydro-central electric stations is 1,756,791 hp. Fuel auxiliaries installed as standbys in these hydro stations bring the total installed primary capacity up to 1,873,989 hp., connected to 1,449,180 kva. dynamo capacity. The total capital invested in these central stations, inclusive of transmission and distribution systems, is $369,464,961, or an average of $210 per installed primary horsepower.

Scientific Control of the Filter Station—V

General Discussion and Summary of Features on Filter Press Operation—Types of Presses and Their Application—Materials Used in Construction of Presses—Pressure Devices—Scope of Centrifuging, Decantation and Flotation*

BY ARTHUR WRIGHT, M.E.

WHEN consideration is given to the fundamental principles of filtration in designing the machine and in operating it, no other system is as simple, direct and positive for the clarification of liquors handled in the industries. When, however, the operation or design of the filter is faulty, centrifugals, decantation methods, flotation schemes, etc., can be substituted and prove more economical.

It is rare that the work done in one operation by a filter can be duplicated by other methods without repeating the operation or supplementing with the use of a filter. The scum from flotation machines is washed and dried in filters, the residues from decantation installations dewatered in a filter and it is common to complete the clarification of liquids issuing from continuous centrifugals through a clarifying filter. Such methods savor too much of "two bites at a cherry" and can scarcely be considered when the correct filters are installed and operated properly.

TYPES OF PRESSES AND THEIR APPLICATIONS

One cause for the substitution of filters is found in faulty design. This is not serious when insufficient filter area or cubical caking capacity has been provided, for such troubles are overcome by additional machines. When, however, wrong types are employed, real difficulties arise. It is becoming better recognized that no one filter can satisfy all requirements and that some types are better for some specific duties. The following classification meets general conditions although local considerations may require radical modification in it:

Plate and Frame Filter Presses—Dry discharge; material requiring frequent filter cloth removal; acids, saline liquors in machines of wooden construction.

Vacuum Leaf Filter—Acid filtration; open tank.

Pressure Leaf Filter—Generally applicable to all materials, but less satisfactory on acid liquors and those containing too freely filtered solids.

Vacuum Continuous Filters—Free-filtering solutions not too hot.

Vacuum Dewaterer Hoppers and Rotating Sand Tables—Crystalline or granular solids too fine for good centrifugation or corrosive to centrifugals.

The matter of design does not end with the selection and construction of the filter best suited for the material in hand, but must include the layout of the machine in the plant. It is most important that the layout be made so that the operator can conveniently observe the operation and handle the valves.

MATERIALS USED IN CONSTRUCTION

When handling acid liquors the amount and nature of the acid present will dictate the materials of construction to be used. But little reliance should be put on protective paints even when handling weak liquors and at relatively low temperatures. The coating is likely to be imperfect even when successive coats are applied, due to the practical difficulty of getting a clean, dry surface on which to apply the coating. The bond between the coating and the metal or material used is not great at its best, and one small exposed point is sufficient to soon nullify the whole coating. Enamel coatings are thoroughly resistant when well applied and free from cracks. Difficulty with this type of coating arises when working on liquors the temperature of which varies from room temperature, for the metal expands at a rate different to that of the coating and cracks develop in the coating. Much improvement in this regard has been effected by enamel manufacturers, and there is hope that eventually this difficulty will be overcome. Lead is highly resistant, but has the unfortunate property of expanding without contracting correspondingly. This is what gives the open tank filters such an advantage, for the creeping of the lead is in no degree as serious as with closed containers. In weak acids several alloys are put out which stand up sufficiently to be practical materials of construction. Here, however, as with the use of monel metallic filter cloths, the design must not allow local electrolytic action to be set up by the use of two dissimilar metals or alloys whose electrical conductivities are not approximately equal.

Alkali filtration prior to the advent of metallic cloths was a troublesome if not an impractical process for industrial work. Metallic cloths are today practical mediums capable of withstanding the action of the strongest caustic liquors, but there are principles to be observed if their application is to be economical or efficient. Most alkaline liquors carry materials in suspension or in solution that have a tendency to scale formation. When handling such materials it is almost imperative that an open weave of cloth be used, for the scaling effect is rapid upon the filter medium due to the lower pressure on the outlet of the leaf often being sufficient to induce evaporation with the consequent scale deposit. Obviously a closely woven or rolled cloth is rendered impenetrable quicker than a more open cloth.

BACK PRESSURE AND SUCTION OPERATION

In closed delivery pressure filters scale formation can be lessened and in some cases eliminated by maintaining sufficient pressure on the outlet of the leaves. With hot liquors this pressure lessens the boiling effect at the surface of the medium and with supersaturated liquors crystallization is retarded or eliminated when the liquor is under pressure. The amount of back pressure required is a variable with the material being

*For Parts I, II, III and IV, see CHEM. & MET. ENG., vol 22, Nos. 22, 23, 24 and 25, June 2, 9, 16 and 23, 1920, pp. 1,015, 1,077, 1,119 and 1,201.

handled, but it will often be found sufficient when a standpipe is run to the floor above. Good design will make this a U pipe, broken at its high point to prevent any siphon action, and returning the effluent within the observation of the operator. Such a back pressure must operate to decrease the flow, but the amount of decrease can be offset with a higher pump pressure. Too many times this decrease is exaggerated. This same argument arises where a suction is put upon the outlet of a pressure filter. In either case the effective working pressure is the difference in pressure between that in the filter outside the leaves and that inside the leaves. Consequently a back pressure simply subtracts from and a suction simply adds to the effective pressure in pounds per square inch and surely the simplest expedient to increase the working pressure is to increase the pumping pressure.

When handling weak acids or alkalis with cotton cloths, provision should always be made to keep the cloths wet. If allowed to dry, the weak liquid becomes concentrated and will eat into the cloths. When a press is standing idle, it is good practice to fill it with water or to remove the cloths and submerge them.

Surmounting Difficulties of Vacuum Filters

Some important filter installations have been made of intermittently operated type filters where, from the nature of the material, continuous type filters would seem to have been the better machines. In these cases the continuous filters were found lacking by reason of their inability to deliver a positively brilliant filtrate and to hold their vacuum due to the excessive cracking of the cake when air dried. Both of these difficulties are surmountable, and continuous filters should have been used. To overcome the clarity objection the valve should have been constructed with another outlet which registers with the arc in which the filter cloth first dips into the liquor and the initial cake is formed. Here is the only opportunity for cloudy liquor, and the delivery into this outlet should be returned to be refiltered. For the second there is no good reason, with drum type filters at least, for blanking off the valve at the point where the cracks allow free air to pass through. In this way the capacity of the vacuum pump is maintained for effective suction and will be found well able to hold the required vacuum.

Means of Forcing Liquids Through Presses

The choice of pump to be used in pressure filtration is a matter of more moment than simply to supply sufficient pressure. Oscillating pumps have little to recommend their use in filtration, for the rising and falling pressure exerts a hammer-like action on the cake being formed and increases its resistance without adequate returns. Also, these pumps, even when supplied with ball valves, give much annoyance by the poor seating of the valves due to the grit and other solids of suspension wedging in the valves. The montejus system of feeding filters is without doubt the best from the filtration point of view, but is costly in compressed air consumption. Centrifugal pumps are becoming more and more popular for this class of work, and for most materials they are excellent. It is when handling flocculent precipitates and when the pump is too large for the outflow of effluent that there is any difficulty with this type of pump. In such cases the rotor becomes an agitator that is too effective in breaking up the flocculent precipitates whose preservation is necessary for good filtration. In overcoming this difficulty the rotary positive displacement pump is becoming more and more generally used and its freedom from valve troubles and oscillating pressures surely warrants its use. Provision must positively be made against excessive pressure occurring in the filter when using this type of pump, for they develop pressures dependent upon the power of their drive.

A common fault often met with is lack of uniformity in the percentage solids fed to the filters. Good filtration calls for a uniform mix of those solids that settle readily and those which settle with difficulty. This requires the use of efficient agitators and too much emphasis cannot be placed upon the admirable work now being done by the non-swirl agitators on the market.

Decantation and Flotation

Continuous decantation systems are highly economical methods for the handling of large volumes of liquors the solids in which settle readily and leave a satisfactorily clear supernatant liquor. Their low labor and operating costs as well as their automatic operation are distinct advantages. They are especially applicable for the handling of calcium sulphate thrown down from phosphoric, oxalic, citric and similar acids, for they are easily constructed acid proof to these materials and effect results seldom approached by filters working on the same liquors. By using weak liquor washes on the successive settlings so that the settlings progress from strong to weak liquors with a final mixing with fresh water, while the supernatant liquors advance from weak to strong liquor, all water entering the system leaves it as strong liquid and the settlings are discharged from the system low in soluble content. The final settlings can then be handled on a continuous type filter, if desired. The large area required for such an installation is prohibitive in some plants, but it will often pay to construct a new department for an installation.

Flotation methods of separation are effective in clarifying liquors the solids of which are capable of being propelled upward by reason of the bombardment of the fine air bubbles ascending through the liquor. In handling greases, gums, fats, etc., this method of separation has much to commend itself, for such materials are difficult to filter and do not settle or float readily.

The advance that has been made in clarification methods and apparatus by Americans is a just cause for congratulation for every citizen of our country. But plant superintendents and operators must still strive to overcome the inertia of being too easily satisfied with results obtainable in their plant, for true economical production can be had only by maintaining equipment and processes up to their maximum efficiency. It may not be amiss to report that some companies in their wisdom have periodic investigations made throughout their plants and count the expense well merited when the reports simply commend present working without making suggestions for improvements. The writer has endeavored to have such investigations inaugurated, for they are signs of true progress and the surest means of preventing dry rot in any organization. Along these lines it is also gratifying to note that more and more concerns are taking up the slogan "Instruct the Operator," for he, in the last analysis, should be the filter expert in his department if the company is to have the most efficient plant.

Motion of Droplets and Particles in the Field of the Corona Discharge

By an Appropriate Arrangement of Apparatus the Paths of Particles in Electrostatic Fields Were Determined—While Four Different Effects Can Be Distinguished, the Corona Discharge Is Largely Responsible for the Action of Cottrell Precipitators

BY RICHARD C. TOLMAN AND SEBASTIAN KARRER*

THE use of the corona discharge for the precipitation of fumes and smokes as in the Cottrell precipitator and for the production of chemical reactions as in commercial ozonizers has become a matter of considerable technical importance[1] It seemed to us possible to obtain a clearer idea of the nature of such discharges by following the behavior of droplets of liquid or small solid particles in the field of a corona current. The motion of these particles was found to depend not only on the potential gradient at the particular point in the field where the particle is located, but also on the type of ions present which could be adsorbed by the particle. The method is thus capable of giving considerable information as mechanism of the corona discharge.

Instrumental Set-up

The apparatus used consisted essentially of a transformer to provide the high voltage necessary for the corona current, a kenotron for rectification in case direct current was desired, a discharge chamber consisting of a central wire between two parallel sheet metal plates, jets for introducing droplets of liquid or solid particles into the corona field, electrostatic voltmeters for measuring the potential between the wire and the plates, an arc for illuminating the droplets or solid particles, and a camera for photographing their motion, all as shown diagramatically in Fig. 1.

The transformer was a Thordarson, wireless transformer, Type P, with an adjustable magnetic shunt giving potentials from 0 to 20,000 volts.

The kenotron was a General Electric low voltage kenotron. Most of the experiments were made with a single kenotron. It was found, however, that the general nature of the results was unchanged by the use of a transformer with split secondary and two kenotrons, thus providing a steadier direct current than with the apparatus connected as shown in the diagram.

The discharge chamber was constructed from two sheet tin plates 6 x 8½ in. placed 2 in. apart. The central wire was nichrome, 0.011 in. in diameter.

Jets for introducing the liquid droplets were made of glass drawn down to give a fine stream. The liquids were forced through under pressure, provided by a definite head of water, or by gas from cylinders maintained at a constant pressure with the help of a mercury manometer. The jet was arranged so that the droplets fell in a stream parallel to the central wire, in a line directly between the wire and one of the plates, and were adjustable as to distance from the wire.

Arrangements were made for grounding the jet when desired by introducing a fine wire into the jet close to its point of issue. In the case of a non-conductor like turpentine, to obtain the desired earthing effects it was necessary to introduce the wire into the stream after it actually left the nozzle. In the case of water the wire could be anywhere near the tip.

Electrostatic voltmeters were of the Braun type and General Electric attracted-disk type.

The arc was focused on a small hole in an opaque screen and the beam of light passed through a slit to limit the beam and remove stray light which would be reflected from the plates. The angle between the beam and the horizontal was adjusted to give the best illumination and this was obtained at an angle of about 28 deg.

The camera was provided with a lens having an effective aperture of 1 in. and a focal length of 4½ in. Exposures lasted for about ⅔ sec. and the lines shown in Figs. 2 to 9 illustrating this article are each one the path of a single illuminated particle. This time of exposure was found sufficient to give the total path of

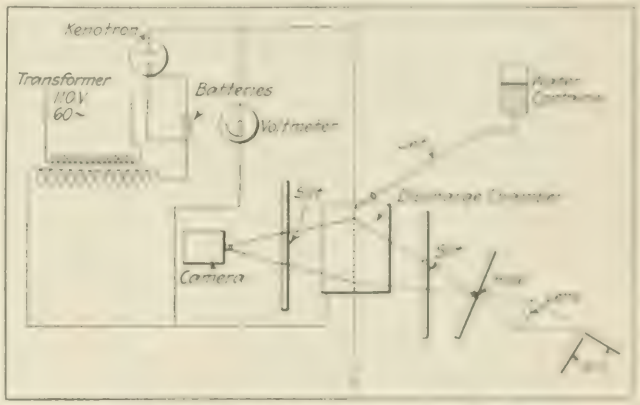

FIG. 1 DIAGRAM OF APPARATUS USED

the particle across the field of the plate. With shorter exposures it was possible from the length of path recorded to calculate the velocity of the fall of the particles, which in the case of the liquids with the pressures employed was in the neighborhood of 10 to 20 cm. per sec.

Experimental Results

In order to describe the motion of droplets and particles in the field of the corona discharge, we have found it convenient to distinguish four different methods by which the droplets may obtain an electric charge—namely, (1) by electrostatic induction, (2) by conduction from the earth when the jet is grounded, (3) by the adsorption of gaseous ions, present in the field

Contribution from the Fixed Nitrogen Research Laboratory.

[1]The technical importance of the corona discharge was particularly called to our attention by the Bureau of Mines, which provided funds for a survey of existing Cottrell precipitating installations.

FIG. 2. WATER FALLING THROUGH NON-CHARGED FIELD
FIG. 3. INSULATED STREAM OF WATER ATTRACTED TO GROUNDED WIRE. PLATE AT —4800 VOLTS

of the corona discharge, and (4) by direct contact with the central wire. We shall now proceed to the discussion of these phenomena under the headings, "Induction Effect," "Earthing Effect," "Corona Effect" and "Contact Effect."

Induction Effect

When a stream of water was introduced into the field between the wire and plates, there was a general tendency noticed for the jet as a whole to bend toward the wire. This is apparently the familiar phenomenon of the motion of a particle having no initial charge toward the more intense part of an electrostatic field. This phenomenon results from the fact that charges of equal magnitude are induced on opposite sides of the particle, and since those on the side of the more intense field (in this case on the side of the wire) experience the more intense electrostatic force, the particle as a whole moves into the intense part of the field.

This effect is illustrated by Figs. 2 and 3. The former photograph shows the stream of water falling through the field of view without any potential applied to the discharge chamber. Fig. 3 shows the bending of the stream toward the wire owing to the described induction effect. In order to make it certain that this induction does exist and that the bending of the stream is not caused by the leak of electricity from the earth into the water, the water was insulated and the wire itself earthed, so that any leak to the water would give it a charge of the same sign as the wire and hence lead to motion away from the wire. In spite of this, the jet bends toward the wire as shown in Fig. 3, clearly demonstrating the induction effect.

It will also be noticed that the application of the electrostatic field leads to a spreading out of the stream of water. This may be partly due to the greater induction effect acting on the particles on the side of the stream nearer the wire, partly due to an actual separation by induction of electricity to the two sides of the stream, and partly due to the mutual repulsion of the different parts of the stream if it as a whole gets an electric charge by leak.

With a non-conductor like turpentine the induction effect could not be obtained. With small particles of aluminum and zinc the induction effect was very noticeable.

Earthing Effect

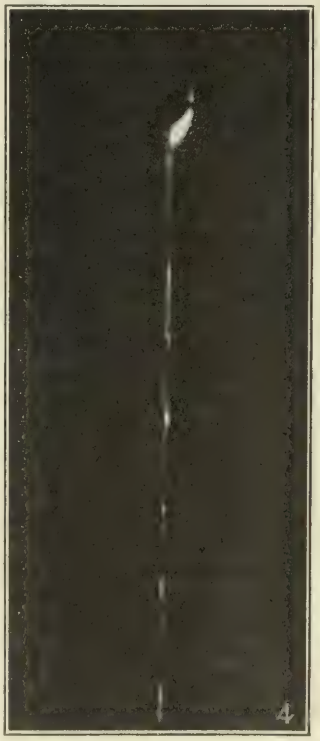
As already described, arrangements were made so that the stream of material issuing from the jet could be earthed, and the effect then determined of earthing either the central wire or the plates. At voltages which were not so high as to make the effect disappear in comparison with the corona effect, the motion of the earthed stream of droplets or particles toward the unearthed electrode was very marked. This is shown in Figs. 4 and 5.

In both these experiments the jet was earthed. In the first case the plate was also earthed, driving the jet sharply to the wire; in the second case the wire was earthed, driving the jet to the plate.

As might be expected, it was very difficult to obtain a decided earthing effect with turpentine because of its low conductivity. Benzyl alcohol showed less earthing effect than water; benzene and petroleum oil a very slight earthing effect. In the case of our metal particles, which were fairly large and of course of high conductivity, the separation of charges was so great that the induction effect always made the particles go toward the wire without reference to the earthing.

Corona Effect

As soon as the voltage between the central wire and the plates has been raised to a point high enough so that appreciable current begins to flow, as indicated by the well known hissing noise of the "silent" discharge,



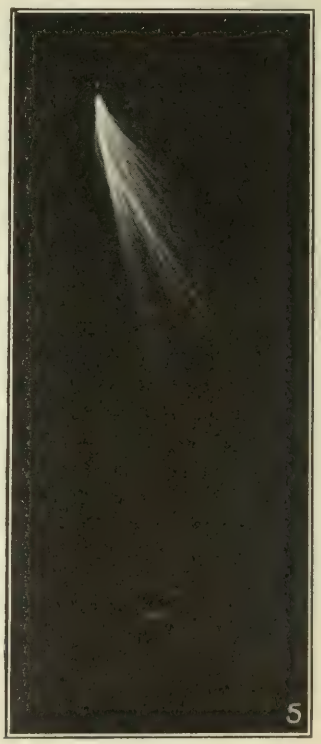


FIG. 4. GROUNDED WATER BENT SHARPLY TO WIRE AT —2700 VOLTS. PLATE EARTHED
FIG. 5. GROUNDED WATER JET DRIVEN FROM EARTHED WIRE AT LEFT (NOT SEEN) TOWARD PLATE AT +2700 VOLTS

a new effect, which we have called the corona effect, becomes of great importance in determining the motion of the particles or droplets. Experimentally we find, under such conditions of high voltage, that the particles have a great tendency to assume a charge of the same sign as the central wire and move away from it. This corona effect occurs whether the central wire is positive or negative. If the plate is earthed and the jet of water also earthed, some of the particles can be forced toward the wire against the corona effect, at least for part of their path. With turpentine, the corona effect always predominates greatly over the earthing effect. With liquids of conductivity intermediate between turpentine and water the ratio of the corona effect to the earthing effect has an intermediate value.

The corona effect for benzyl alcohol is illustrated in Figs. 6, 7 and 8. In these experiments the plate was earthed and hence at a low voltage the leak to the benzyl alcohol from earth was enough to force the stream to the wire by the earthing effect which we have already discussed (Fig. 6). At a high voltage, however, as shown in Fig. 8, the corona effect completely overcomes the earthing effect.

FIGS. 6, 7, AND 8. INSULATED BENZYL ALCOHOL STREAM UNDER INFLUENCE OF CHARGED WIRE (AT LEFT) AND EARTHED PLATE

Fig. 6 at + 2500 and Fig. 7 at +4000 volts show earthing effect. Fig. 8 shows corona effect preponderating at +8000 volts

It should be noted that the corona effect is of main importance in determining the behavior of Cottrell precipitators. Theoretically, we may explain this corona effect by reference to the probable mechanism by which the ionization necessary for carrying the corona current is produced. In the neighborhood of the central wire, the potential gradient is initially steeper than in the main portion of the field, owing to the geometrical configuration of the apparatus. Hence the major part of the ionization by collision necessary for carrying the current will take place in the neighborhood of the wire. Ions produced in this "ionization region" of the opposite sign to the central wire will be attracted to the wire and ions of the same sign as the wire will be repelled to the plates. Hence inside this "ionization region," ions of the opposite sign to the wire will predominate, thus increasing the initial steepness of the potential gradient which leads to the formation of the "ionization region." Outside of this small "ionization region" we may expect ions of the same sign as the central wire to predominate in number, and hence if our droplets or particles have anywhere near equal adsorptive affinities for positive and negative ions, they will obtain in general the same charge as the central wire and move toward the plate.

Looking at this theoretical explanation from the reverse point of view, it seems to us that the observed experimental facts demonstrate with a high degree of certainty that the space charge in the field of a corona discharge, except in the immediate neighborhood of the central wire, is of the same sign as the central wire. This disagrees with the conclusions of Booth[2], who found the density of the space charge to be zero over the largest part of the corona field. His method, however, involves besides the original uncertainties inherent in any method of using an exploring electrode, two successive graphical differentiations, obtaining quantities of nearly the same magnitude, which then have to be subtracted one from the other in order to obtain the desired density of the space charge.

The fact that particles and droplets pick up from the major portion of the corona field the same charge as the central wire with great readiness is further shown by their behavior in the field of an alternating corona current. This is illustrated by Fig. 9. Here, in spite of the fact that the current is reversing sixty times a second, the motion of the droplets of turpentine is almost uniform toward the plate. In other words, inside of a small fraction of a sixtieth of a second, the space charge and the consequent charge on the droplets reverse in sign. This observation explains the fact that it is possible to obtain some precipitation in the Cottrell process using alternating current.

Contact Effect

A fourth method by which particles may obtain a charge in the field of a corona current is by direct contact with one of the electrodes. In particular they may come in contact with the central wire, obtain a very heavy charge from the central wire and then be repelled with great violence right through the ionization region to the plate. This is shown in Fig. 10.

Corroborative Experiments With Single Particles

In order to confirm the existence of the induction, earthing, corona and contact effects by which a charge may be imparted to a particle, experiments were made on single particles suspended in the field on glass fibers and on thin metal wires. The phenomena expected were reproduced. At high potentials the particle was always repelled from the central wire by the corona effect, at low potentials the particle could be made to move toward either electrode desired by taking advantage of the

[2] *Phys. Rev.* (2), vol. 10, p. 266 (1917).

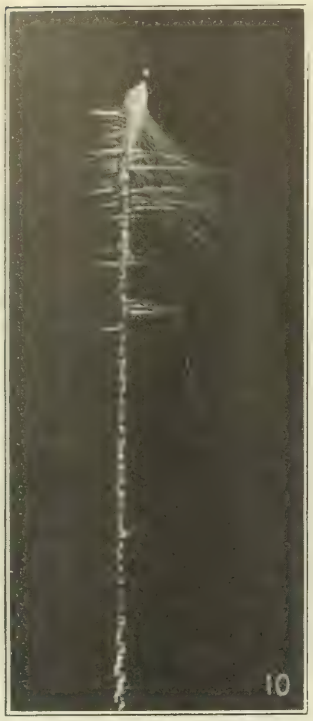

FIG. 9. INSULATED TURPENTINE DROPLETS DEFLECTED FROM WIRE CHARGED WITH 60 CYCLE ALTERNATING VOLTAGE OF ±9000. PLATE GROUNDED

FIG. 10. VIOLENT EXPULSION OF EARTHED WATER DROPLETS ON COMING IN CONTACT WITH WIRE AT +8000 VOLTS

earthing effect, and at any voltage the particle was repelled from the central wire after coming in actual contact with it.

Waterfall Effect

In connection with our experiments on the earthing effect, it was noticed in the case of water that the jet breaks into finer particles when positively charged than when negatively charged. This apparently means that the surface tension of water is lowered more by a positive charge of electricity than by a negative charge.

This conclusion would seem to stand in agreement with the phenomenon known as the waterfall effect—namely, that droplets of water naturally have more tendency to assume a positive than a negative charge of electricity. This would of course be expected if the surface tension of water is lowered more by positive than by negative electrification, since that would mean that the potential energy of the droplet is more lowered by positive than negative electricity, which means of course that there is more natural tendency for water to pick up positive than negative electricity, since in general electrostatic systems rearrange themselves in the direction of minimum potential energy.

Conclusion

It is believed that this article demonstrates the existence of four methods by which particles in the field of a corona discharge may obtain charges of electricity—namely. by induction, by conduction of electricity from the earth, by the adsorption of ions present in the corona field, and by actual contact with an electrode. The motion of the particles is determined by the charge which they receive by one of these methods and of course of the potential gradient.

It is shown that the space charge in the major part of the field of the corona discharge is of the same sign as the central wire, in contradiction to the conclusions of Booth.

It is believed that the adsorption of ions having the same charges as the central wire is the underlying process in the action of Cottrell precipitators.

An incidental observation on the behavior of streams of water shows that they break up into finer particles when positively charged than when negatively charged. This was shown to be in accord with the well-known waterfall effect.

Potash Mines of Alsace

French potash and the conditions of that industry, as viewed since the Alsatian district was incorporated in the national domain, are reviewed by the American Trade Commissioner in Paris.

With the exception of the Société de Kali Sainte Thérèse, under Alsatian-French control, all of the potash mines in Alsace were owned and operated by German companies before the war. The first company to extract potash in Alsace was formed in 1906. At the time of the armistice there were fourteen companies, controlling 109 concessions and seventeen mines, these companies being, in turn, controlled by four large groups. The Sainte Thérèse group controls thirty-three concessions, the Deutsche Kaliwerke group controlled forty-eight concessions, the Wintershall group thirteen concessions, and the Hohenzollern group fifteen concessions. The German holdings, under liquidation since the armistice, are being operated for the account of the French Government.

300 Per Cent Increase Since Armistice

Until the Alsatian mines passed under French control the German Government regulated the sale of potash from them and from the German mines in order to prevent overproduction and to keep prices at a uniform level. During the year 1913 the German and Alsatian mines produced 11,600,000 tons of crude potash, 6 per cent of this amount, or approximately 696,000 tons, being the quota from the Alsatian mines. When the Germans left, some of the mines were found to be in a flooded state, and considerable pumping and repairs were necessary. Since the armistice the production has been increased by more than 300 per cent.

The total production of crude potash for 1919 was about 550,000 tons. During this period the average production per miner was increased from 0.933 ton per day to 1.48 tons per day.

The estimated production of crude potash from the Alsatian mines during 1920 is 1,320,000 tons, or about 220,000 tons of pure potash. It is expected that this output will increase to 2,040,000 tons of crude, or 340,000 tons of pure potash, in 1921, and to 2,340,000 tons of crude, or 390,000 tons of pure potash, in 1922.

Lack of Transport Curtails Export

Since the armistice the United States has been unable to secure anything like the quantity of potash it urgently requires. This is due almost entirely to the transport crisis in France. The lack of railway transport likewise reduces the shipments of coal necessary for the reduction of the higher grades of potash.

It should be remarked that the mines now in operation in Alsace are alone capable of supplying the world's needs. Otherwise expressed, it is merely a matter of stimulating production to the required level. —*The Review*, May 15, 1920.

Economic Aspects of the Chilean Nitrate Industry*

A Summary of the Economic Features of the Chilean Nitrate Industry, Showing the World-Wide Requirements of This Chilean Natural Product for Agricultural and Industrial Purposes—Work of the Nitrate Producers' Association and Outlook for Future Developments

CHILE is the only country in the world known to contain commercially important deposits of nitrate of soda, a product which has a wide variety of uses, but is best known as a valuable fertilizer. Two grades of nitrate are produced: 95 per cent, or ordinary nitrate, which is used for fertilizer purposes, and 96 per cent, or refined nitrate, which is used for manufacturing purposes. Before the war approximately 75 per cent of the nitrate marketed was of the lower grade. Private business in Chile and government revenue are both dependent on the prosperity of the nitrate industry, since this one product ordinarily constitutes nearly 80 per cent of the country's exports, and the export tax on nitrate and its principal byproduct, iodine, constitutes more than half the government's total income.

There is a great deal of speculation concerning the probable duration of the beds, but the very range of the conclusions arrived at shows on what inadequate data they have been based. One expert estimates the explored deposits to contain 240,000,000 metric tons of nitrate, and calculates the contents of the unexplored region to be twice as large. According to these figures it would require over 240 years to exhaust the supply at the present rate of production. Other estimates are less optimistic and set a much earlier date for the exhaustion of the beds.

The nitrate region consists of five important districts.[1] The relative importance of the principal districts is shown in Table I, giving the number of oficinas producing plants operated in each district, the extraction of caliche (the raw product from which nitrate is produced), and the amount of nitrate derived, during 1917:

TABLE I PRODUCTION OF THE PRINCIPAL NITRATE DISTRICTS IN 1917

Districts	Oficinas in Operation	Caliche Mined Metric Tons	Nitrate Produced Short Tons	Nitrate Produced Metric Tons
Tarapaca	76	10,330,984	1,433,213	1,302,921
Tocopilla	7	1,822,334	250,690	227,900
Antofogasta	30	9,172,026	1,184,225	1,076,568
Aguas Blancas	7	1,066,473	160,149	145,590
Taltal	9	1,923,257	272,858	248,053
Total	129	24,315,074	3,301,135	3,001,032

Caliche differs in appearance and composition in various zones. It usually contains (besides sodium nitrate) sodium chloride, sodium sulphate, potassium nitrate, sulphates of lime and magnesia, sodium iodate and sodium biborate in varying proportions. The sodium nitrate content varies from less than 10 per cent to over 70 per cent, the average sodium nitrate content of the caliche extracted during 1917 being 17.48 per cent.

Iodine, the most important byproduct of the nitrate industry, is extracted from the liquor which remains after the nitrate has been precipitated. Although some sodium iodate is contained in practically all caliche, iodine is produced by only a portion of the nitrate companies, and the output of these companies is carefully regulated by a producers' trust in order that the limited market may not be overstocked. The average pre-war exports amounted to approximately 475,000 kilos annually; but during the war, the exports were much larger: 708,800 kilos in 1915, 1,323,000 kilos in 1916, and 759,000 kilos in 1917. Germany was the principal purchaser of iodine before the war, the United States second, and Great Britain third.

Another byproduct, nitrate of potassium, is engaging the attention of various experts. One chemical engineer asserts that this salt exists in the caliche throughout all parts of the nitrate region and that the caliche used by at least a hundred of the oficinas contains from 1 to 2 per cent. An American company is reported to have perfected a refrigerating process by means of which it can manufacture this byproduct at small cost.

Cost of Labor and Supplies in the Nitrate Fields

The laborer in this arid zone requires great strength and endurance under the most trying of living conditions. The nitrate region produces no fresh fruits or vegetables, and he is obliged, therefore, to live largely on imported canned goods. He receives a far higher wage than any other class of Chilean laborer, but on the other hand the cost of all the necessaries of life is exceedingly high. To compensate the laborer for the hardships of the situation, the nitrate operators are compelled to provide living quarters for employees and their families and to maintain stores where they can purchase food, clothing and household furnishings.

At the outbreak of the war, 53,000 laborers were employed in the nitrate fields. Immediately afterward this number materially decreased, but in 1915 it began to increase again and in 1917 had reached 56,000. Of this number, about 43,000 were Chileans, and the remainder largely Peruvians and Bolivians. Before the war the average daily wage of the nitrate laborer was 6.48 Chilean paper pesos, and in 1917 the average wage was 6.81 Chilean paper pesos. (In 1914 the exchange value of the paper peso was about 20c.; during the war its value fluctuated between 14c. and 33c.)

Nitrate producers must import all their supplies, such as fuel, machinery and parts, and bags in which to ship the nitrate; and the cost of all these commodities has increased materially during the last few years. One manufacturer reported in 1918 that petroleum, which had formerly cost 41½s. ($10.98) per ton, then cost 150s. ($36.45); that the cost of coal had increased from 29s. to 115s. (from $7.06 to $27.95); and that jute bags, which he had formerly purchased for 3½d. (7c.) each, had reached the high figure of 22d. (46c.). A million tons of fuel was consumed in nitrate mining and refining in 1917. Of this total 65.5 per cent was

*Abstracts from Latin American Circular 67, Bureau of Foreign and Domestic Commerce.

[1] See CHEM. & MET. ENG., vol. 22, No. 14, p. 655.

petroleum, 28.6 per cent coal, and the remainder such fuel substitutes as straw and grain. Apparently no wood was used. Before the war most of the coal was imported from Great Britain. Petroleum comes principally from Mexico and the United States.

Nitrate is packed for shipment in jute bags holding about 200 lb. each. These bags are imported from India and about 30,000,000 of them are ordinarily used each year.

Relative Importance of Native and Foreign Companies

The greater part of the capital invested in the nitrate industry is Chilean and British. The amount of American capital in the field is relatively small but is increasing. German interest in the business was growing until checked by the war. The comparative importance of the native and foreign nitrate plants can be judged by their proportionate share in the total production for the year 1917, as shown in Table II.

TABLE II. COMPARATIVE IMPORTANCE OF NATIVE AND FOREIGN NITRATE PLANTS

Nationality	Number of Oficinas	Annual Production—Short Tons	Annual Production—Metric Tons	Per Cent of Total
Chilean	54	1,399,995	1,272,723	42.41
British	44	1,246,622	1,133,293	37.76
German	7	177,148	161,044	5.37
American	2	86,404	78,549	2.52
Peruvian	7	86,549	78,681	2.62
Spanish	4	76,639	69,672	2.32
Slavic	7	179,465	163,150	5.44
Others	4	51,613	46,920	1.56
Total	129	3,304,435	3,004,032	100.00

Sixty per cent of the nitrate manufactured by Chilean companies is the product of five large concerns, Compañía de Salitre de Antofagasta, Compañía Salitrera El Loa, Compañía Salitrera El Boquete, Compañía Salitrera Lastenia, and Compañía de Salitres y Ferrocarril de Agua Santa.

La Compañía de Salitre de Antofagasta is the oldest and one of the most important nitrate producers in the country. It owns a strip of nitrate land about 32 km. long by 4 km. wide in the Antofagasta district and employs 15,000 men. Its oficinas consume 80,000 tons of coal yearly, and the public stores which it has established at its plants purchase 8,000,000 paper pesos worth of general merchandise annually. It produced 340,000 metric tons of nitrate during 1917, 10 per cent of the total amount manufactured during the year. In connection with its nitrate business, the company has built up a large general import and export business, for which it maintains a fleet of four tugs and about a hundred barges at Antofagasta.

Compañía Salitrera El Loa owns about 14,000 acres of land in the Antofagasta district about 95 miles from the coast on the Antofagasta and Bolivia Railroad. It has seven oficinas and produced nearly 212,000 tons of nitrate during 1917. Compañía Salitrera El Boquete has two oficinas located in the Antofagasta district and produced 94,000 tons of nitrate in 1917. Compañía Salitrera Lastenia, also located in the Antofagasta district, has two oficinas and produced 79,000 tons of nitrate during 1917. Compañía de Salitre y Ferrocarril de Agua Santa owns six oficinas in the Tarapaca district and manufactured 55,000 tons of nitrate in 1917.

Important Foreign Companies

The 1917 statistics show eight English companies whose annual production of nitrate amounted to over 50,000 metric tons. The combined output of these companies represented over 60 per cent of the total quantity of nitrate manufactured by English firms during that year.

There are four German nitrate firms. These companies are equipped to produce considerable quantities of nitrate, but were forced to close many of their plants during the war, and, therefore, their 1917 production does not represent their normal output. Compañía Salitrera H. B. Sloman owns four oficinas in the Tocopilla district, two of which were open in 1917 and produced 58,000 tons of nitrate. Compañía Salitrera Alemana owns four oficinas in the Taltal district, only one of which was operated during 1917, producing 42,000 tons of nitrate. Salpeterwerke Gildemeister A. G. owns three oficinas in the Tarapaca district, all of which were operated during the year; their total output was 50,000 tons. Salpeterwerke Augusta Victoria A. G. owns only one oficina. This oficina is located in the Antofagasta district and produced 10,000 tons of nitrate during the year.

The Grace Nitrate Co. and the Du Pont Nitrate Co. are the only American companies producing nitrate in Chile. The Grace company owns a well-equipped oficina in the Tarapaca district where it employs more than a thousand men. The company produced 42,000 tons of nitrate during 1917, all of which was sent to the United States. The Du Pont company has one oficina in operation in the Taltal district and is building a second in the Tarapaca district. Its nitrate production for 1917 was 35,000 metric tons.

The firm of Baburizza, Lukinovic y Cia. was founded by two members of the Slavic colony in Chile and one Chilean, and might be considered Slavic, although it is registered in Chile. This company owns three oficinas and about 69 sq.km. (1 sq.km. = 0.386 square mile) of nitrate land in the Antofagasta district. It employs 2,200 men at its nitrate plants and produced 123,000 tons of nitrate during 1917.

Markets for Chilean Nitrate

The market for nitrate steadily increased and Chile's profits from the exploitation of this natural monopoly increased proportionately until the beginning of the war, when the European demand for nitrate fertilizers practically ceased. Fortunately for the nitrate producers and for Chile, however, the Allies soon found that they needed this product for the manufacture of high explosives; and needed it so badly that they were willing to pay high prices, allocate shipping space to carry it from Chile to the United States and Europe, and furnish the necessary supplies to the producers in Chile; as a result, the intense depression which had begun with the declaration of war was quickly succeeded by an unparalleled prosperity.

TABLE III. CHILEAN NITRATE PRODUCTION AND EXPORT 1909–1918

Year	Production—Short Tons	Production—Metric Tons	Exports—Short Tons	Exports—Metric Tons
1909	2,322,057	2,110,961	2,348,454	2,134,958
1910	2,711,957	2,465,415	2,569,535	2,335,941
1911	2,773,125	2,521,023	2,694,467	2,449,515

1917	3,304,435	3,004,032	3,053,918	2,776,289
1918	.....	.....	3,256,097	2,960,088

The steady increase of the normal pre-war demand

for Chilean nitrate, the depression occasioned by the outbreak of the war, and the subsequent recovery are all reflected in Table III, showing the annual production and exports for the 10-yr. period 1909-1918.

The cessation of hostilities in Europe brought to a sudden and complete halt the need of nitrate for ammunition manufacture and precipitated a period of depression similar to that of 1914. The decline in the market necessitated the closing of a considerable number of the oficinas and the curtailment of production at others; quotations of nitrate stock slid steadily downward; the efforts of the association of producers to maintain selling prices partially failed and they were forced to yield bit by bit in order to sell even a portion of the nitrate stocks rapidly accumulating on the Chilean coast.

Table IV, giving the comparison of nitrate production, exports and stocks in Chile, by months, for 1918 and 1919, shows the difficulties which this industry has been experiencing. The figures are unofficial estimates and the amounts are given in Spanish quintals (one Spanish quintal = 101.4 lb.), the commercial unit of measure for nitrate.

(a) Statistics not yet available.

Chief Markets for Chilean Nitrate

The United Kingdom, Germany and the United States were the chief markets for Chilean nitrate before the war, the three together taking approximately five-sixths of the total exports during 1912 and 1913. France, Belgium and Holland ranked first among the lesser markets. The statistics of the war years are of relatively little value in gaging the future demand in any country engaged in the European war: Germany and Belgium, formerly good markets, were unable to import any nitrate; the United States, France and Italy increased their imports, but used most of it for ammunition manufacture. From the point of view of the dealer who wishes to estimate the future demand for nitrate, perhaps the most significant development of the years 1917 and 1918 is the marked increase of nitrate exports to Japan.

Table V shows the exports of nitrate from Chile by countries of destination for the pre-war years 1912 and 1913 and the war years of 1917 and 1918.

After the signing of the armistice, the United States Government no longer needed the nitrate purchased for war purposes and transferred the amount on hand from the War Department to the Agricultural Department for distribution to the farmers. This amount, plus a considerable quantity already held by the Agricultural Department, was sold at cost. As long as these stocks were available at low prices, there was little chance for the sale of privately held nitrate, but the last of this supply was disposed of in the spring of 1919 and subsequently all Government restrictions on nitrate imports were removed. The nitrate dealer has a free market once more and, what is of equal importance in his estimation, the Government plants for the manufacture of synthetic nitrate have been closed. Imports of nitrate of soda into the United States for the year 1919 were 407,459 long tons, about 65 per cent of the 1913 imports.

Apparently a relatively small proportion of the nitrate imported into the United States is used for fertilizer purposes. According to the War Trade Board, about 40 per cent is ordinarily used in the manufacture of explosives, 13 per cent for fertilizer, and the remainder for making sulphuric acid and for miscellaneous purposes. The Department of Agriculture reports that 564,000 tons was imported during 1914, of which amount 162,000 tons, about 29 per cent, was used for fertilizer purposes.

European Sales Restricted During 1919

About 80 per cent of the nitrate imported into Europe is ordinarily used for fertilizer purposes. It is said that there was an active demand for these fertilizers last year, but government restrictions, accentuated by the lack of shipping space, greatly restricted sales, especially during the early part of the season when the demand was strongest.

Great Britain had contracted for 680,000 tons of nitrate shortly before the signing of the armistice, practically all of which became available for ordinary market uses, and import restrictions were not removed until the major part of these government stocks had been disposed of. Since the middle of May, when government restrictions were finally removed, imports have been greatly hampered by the lack of available tonnage.

Germany has been unable to import nitrate because of the continuance of the blockade, but it seems unlikely that it would have been able to do so anyway, as at the present depreciated value of the mark, the selling price of nitrate fertilizers would be prohibitively high.

The reduction of acreage under cultivation in France and Belgium has somewhat curtailed the demand for nitrate fertilizers, but it is stated that consumption would have been nearly double what it was during the first half of the year had it not been for the congestion at the ports, the disintegration of the interior transport service, and government restrictions.

Chile has been greatly alarmed by this depression in the market for nitrate and by rumors hinting that nitrate was to be supplanted in Europe and America by two rivals, namely, sulphate of ammonia, a byproduct of coke, and synthetic nitrate produced by electric fixation of atmospheric nitrogen. To fully appreciate this alarm, it is essential to comprehend how dependent the nation is upon this one export.

Chile buys the bulk of its manufactured products abroad and pays the bill with the raw products exported, nearly 80 per cent of whose value is represented

by nitrate sales. Therefore the value of the Chilean peso abroad is directly affected by the market for nitrate, and nearly all private business in Chile is indirectly dependent on the nitrate industry.

Government Aid to Producers

The vital importance of the nitrate industry to the Chilean Government is graphically illustrated by the following facts: For the period 1901-1917 the export duties on nitrate and its principal byproduct, iodine, constituted 62 per cent of the total revenue received; during 1913, the last pre-war year, they constituted 57 per cent of the total revenue; and during 1917, the last year for which these statistics are available, they formed 65 per cent of the total. The government cannot afford to allow the exports of nitrate to decline nor can it afford to have the 50,000 laborers ordinarily employed in the nitrate fields idle.

During the depression of 1914 the government arranged to make temporary loans to the producers in order that they might not have to close their plants. Under this system the nitrate companies desiring them were issued government bonds, which they were at liberty to sell in the open market. These advances were to be guaranteed on nitrate stocks and to be refunded plus the accrued interest when said stocks should be sold. These arrangements have been continued up to the present time, the companies now being allowed to receive not to exceed four paper pesos for each Spanish quintal of nitrate delivered at the port of embarkation and not to exceed three pesos for each Spanish quintal stored at the oficinas. From August, 1914, to December, 1918, government loans to producers amounted to 103,946,000 paper pesos and reimbursement of these loans to 98,570,000 paper pesos. Loans during January, 1919, amounted to 9,561,000 paper pesos.

Further evidence of the government's interest in the welfare of the nitrate industry is afforded by the recent appropriations to the newly established industrial school for nitrate research; by the recognition accorded the scientific society lately formed by a number of Chilean and English nitrate companies; and by two plans recently discussed in Congress. The first of these plans, to centralize sales under government control, has been severely criticized; the second, to alter the basis of the nitrate tax, has been discussed several times but no definite action taken. The nitrate tax, as now imposed, is a fixed amount, 2s. 4d. ($0.568) per Spanish quintal of nitrate exported, and the cost of production varies according to the nitrate content of the raw material exploited and according to the size and efficiency of the reducing plant, wherefore some companies realize much larger profits than others. Under the plan now being discussed the tax would be levied on the profits of the companies rather than on the nitrate exported.

Protective Association Formed by Companies

During the recent crisis a second attempt has been made to organize the nitrate producers into an association which shall limit production and centralize sales, the object being to allow only as much nitrate to be exported as the consuming markets can absorb at a price high enough to afford reasonable profits to the producers. The first association was formed in 1901 and ceased to exist in 1909 because of a disagreement concerning production allotments to certain companies. The present association is the outgrowth of the former association and the Nitrate Propaganda Committee organized by the English companies about 1889 and later known as the Asociacion de Salitre de Propaganda. This association has had headquarters in Chile and has had two distinct prerogatives: To keep a complete statistical record of the progress of the nitrate industry, and to increase the world market for nitrate through the education of the public as to its uses. For this latter purpose propaganda committees have been maintained in France, Germany, Belgium, Holland, Spain, Italy, the United States, Japan, Egypt, Cuba, Australasia, England and Wales.

The directors of this association felt the necessity of forming an organization which would have some control over the entire industry, that this organization should consist of the producers, and that it should be free from any sort of government control. They therefore appointed a committee to study the situation and draw up a plan for such an organization. This plan was presented and accepted at a meeting of the producers held in January, 1919.

Work of the Association

All the Chilean and English producers are now members of this association, and it is reported that the four German companies are to be admitted in the near future. The two American firms, the Grace Nitrate Co. and the Du Pont Nitrate Co., have not joined the association.

The duties of the association may be briefly summarized as follows:

1. To spread nitrate propaganda, commercial and scientific, throughout the world market.
2. To keep a statistical record of the industry.
3. To regulate exports and control production within certain general limits.
4. To fix selling prices periodically to accord with conditions governing the market and factors governing the cost of production.
5. To establish nitrate stocks at convenient ports.
6. To study and encourage new methods of refining and mining.

The association has followed the established custom of selling nitrate f.o.b. Chilean ports. Prices are quoted in shillings and pence per Spanish quintal of 101.4 lb. The association could not hope to sell nitrate at 13s. ($3.163) per quintal for ordinary, or 95 per cent nitrate, and 13s. 6d. ($3.285) for refined, or 96 per cent, the prices at which the Allied Governments were purchasing it at the close of the war, but attempted to fix a selling price of 10s. 1d. ($2.454) for ordinary and 10s. 4d. ($2.514) for refined, a price above the average for any year prior to 1917. As the report of sales issued in October, 1919, shows, however, it has not been able to maintain this price, its average selling price for nitrate sold up to October having been 9s. 0.5d. ($2.20) for ordinary and 9s. 4.2d. ($2.28) for refined, and for nitrate to be delivered between October and March, 1920, having been 9s. ($2.19) for ordinary and 9s. 3d. ($2.25) for refined. At these average prices, it had disposed of 17,358,000 quintals of ordinary and 866,000 quintals of refined up to October, and had contracted for 16,500,000 quintals for future delivery.

Encouraged by the slight improvement in the market, the association raised its price in October to 9s. 7d. ($2.33) per quintal for delivery up to Dec. 15 and 9s. 9d. ($2.37) for later delivery up to June 30, 1920. Between October and December prices were gradually increased until in December nitrate for immediate delivery was sold at 9s. 7d. ($2.33) and for future delivery from 10s. 6d. to 12s. ($2.56 to $2.92).

The profits of the last few years have afforded many of the producers an opportunity to fortify themselves against this anticipated period of depression. The following statistics, compiled from recently published reports, of some of the more important English and Chilean companies illustrate to what extent they have taken advantage of this opportunity.

The fourteen English companies which close their year in December had a total capitalization of £4,189,000 at the end of 1918 and £404,900 outstanding in debentures, against which they had £1,216,359 in reserves and £786,573 in their carry forward accounts. They had distributed £592,275 in dividends for the year, an average of 14.1 per cent, and had added £155,000 to the reserves and increased their carry forwards. (The value of the pound sterling is $4.8665 at normal exchange.)

La Compañía de Salitre de Antofagasta, the largest nitrate producing company, made a profit of 22,305,520 paper pesos for 1918, out of which 11,520,000 was distributed in dividends, 10,000,000 added to funds for exploitation and amortization of property, and the remainder to a contingency fund. The company is capitalized at 16,000,000 paper pesos, has a reserve fund of 2,000,000, a contingency fund of 2,674,955, a fund of 32,000,000 for exploitation and amortization of property, an insurance fund of 2,500,000, and a fund of 2,000,000 paper pesos to provide for fluctuation in exchange.

Compañía Salitrera El Lon, another large Chilean company, made a net profit of £450,314 during 1918, out of which £227,500 was distributed in dividends, £200,000 placed in the fund for amortization of oficinas and land, and the balance placed in the dividend fund.

Compañía Salitrera Lastenia made a net gain of £184,197 during 1918, out of which £124,800 was distributed in dividends, and the remainder placed in the dividend fund. This company is capitalized at £624,000, has a reserve fund of £20,000, a fund of £8,029 for operation, a fund of £14,024 to provide for the fluctuations of exchange, and a dividend fund of £75,795.

Outlook for Future Reassuring

According to the representatives of the association abroad the prospective demand for nitrate fertilizers for use on next year's crop is excellent. The largest problem is that of ocean transportation; indeed so serious is this one factor that the sales for some time to come will probably be limited by the available shipping space and the prevailing freight rates. Uncertain exchange and disturbed political and economic conditions in Europe will tend indirectly to reduce consumption also.

The association reports the present outlook decidedly encouraging, although no spectacular recovery is expected. It is estimated that exports for the present nitrate year (July 1, 1919, to June 30, 1920) will not exceed 30,000,000 Spanish quintals (about 1,400,000 metric tons).

The educational work in the application of Chilean nitrate to the soil has been successfully carried on since the formation of the original association of producers and the resultant demand is expected to continue for a long time to come.

If Chilean nitrate is ever displaced to any great extent in the fertilizer field the process will be so slow as to work little hardship on the producers. Such replacement certainly can never keep pace with the rate of increase in demand for nitrogen fertilizers.

Calibration of an Optical Pyrometer

By W. E. Forsythe

AN OPTICAL or other pyrometer is calibrated by finding the relation between the reading of the scale, whatever that may be, and the temperature of the standard source with which it is compared. In the disappearing-filament type of optical pyrometer the quantities involved are the current through the pyrometer filament and the temperature of a black body when the filament as observed through the eyepiece apparently matches in brightness the black-body image located in the plane of the pyrometer filament.

The direct way to calibrate the pyrometer is to have a black body that can be operated at various known temperatures over the entire range that it is desired to use the pyrometer. This is always very difficult and sometimes impossible. The main trouble is to get a black body that will stand the high temperatures and at the same time it is difficult to get a satisfactory method of measuring these temperatures. Standard black bodies are seldom operated at a temperature higher than that of melting palladium (1,828 deg. K.).

Thermocouples that have been operated for any length of time at this temperature are not reliable in their indications. For the above reasons, when calibrating for temperatures above the range of thermocouples, use must be made of standard melting points or another optical or a radiation pyrometer. There are not many metals that can be conveniently used for this purpose. The two that are most commonly employed are gold (1,336 deg. K.) (deg. K. indicates degrees Kelvin, i.e., absolute Centigrade) and palladium (1,828 deg. K.). There are no metals with melting points between these two that can be used without much trouble due to oxidation.

An optical pyrometer can be calibrated from a black body held at a particular temperature[1]. Since the black body thus used is to be the standard of reference, a standard temperature, that is, one determined by means of a standard melting point, is generally chosen. A very good temperature for such work is that of melting palladium, or the palladium point. There are three reasons for the choice of this point. In the first place, it is about as high a temperature as a platinum-wound furnace can be operated. In the second place, this temperature is about as high as the pyrometer filament will stand if it is to have a long life. In the third place, the temperature of melting palladium is very well known in terms of the laws of radiation and the temperature of melting gold.

Reduction of Apparent Radiation

To calibrate an optical pyrometer from a furnace held at a particular temperature it is necessary to have some means such as a rotating sectored disk (to be described below) or an absorbing glass of known transmission for cutting down the apparent brightness of the incident radiation. If readings are made of the current through the pyrometer filament for an apparent brightness match with a rotating sector or an absorbing glass of known transmission between the pyrometer lamp and the standard black body, there will be obtained a measure, in terms of a current through the pyrometer filament, of a brightness that is some known factor of that of the standard black body at the standard tempera-

[1] C. E. Mendenhall, *Phys. Rev.*, vol. 32, p. 74 (1911).

ture. If monochromatic radiation is used, it is easy to calculate the temperature, T_2, of the black body corresponding to this measured brightness, that is, to this current through the pyrometer filament from T_1, the standard temperature, by the following formula derived from Wien's equation:

$$\log R = \frac{c_2 \log e}{\lambda}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad (1)$$

where R is the transmission of the sector, temperatures on the absolute Centigrade scale, and λ the wave-length used. If the measurements are made with a red glass in the eyepiece, the temperature that would correspond to this fraction of the brightness of the standard black body can be calculated just as before, excepting that in this case the effective wave-length of the red glass for this temperature interval is to be used. By using a number of such sectors, points can be obtained for a curve showing the relation between the temperature and current through the pyrometer filament. In Table I is given the transmission value of a number of sectors and the apparent temperatures, T_2, that would be obtained by their use in connection with a black body held at the temperature of melting palladium.

TABLE I.

Temperatures corresponding to different percentages of the radiation from a black body held at the temperature of melting palladium (1,828 deg. K.) using red glass with an effective wave-length which varies as is shown in column 2. C_2=14,350 μ deg.

Use of Standardized Filament

It is very troublesome to operate a standard black body every time it is necessary to calibrate an optical pyrometer. Much time can be saved if a tungsten lamp with a filament of suitable size is standardized so as to have the same brightness for a particular part of a filament, when observed with the optical pyrometer, as the standard black-body furnace for one or more definite temperatures. Such standard lamps with single-loop wire filaments have been made, calibrated and used in this laboratory for this purpose for several years. The bend in the wire was made somewhat sharp and the center of this loop used as a point of reference. This method has recently been employed by a number of the research laboratories of the country using lamps calibrated at several currents for temperatures between 1,200 and 2,000 deg. K.

For the highest accuracy the tungsten lamp that is to be used for calibration purposes should be standardized with an optical pyrometer using a red glass which is the same as that on the pyrometer to be compared, or correction should be made for the difference. If the effective wave-lengths are known, this correction can easily be made.[2] For practical purposes, however, if similar red glasses are used the error will be quite small.

Tungsten filaments have been found to depart very markedly from Lambert's cosine law in their radiation.[3] To avoid error due to this cause, care must always be taken in determining the temperature of circular filaments to measure the brightness of the central part of the filament. For this reason, the pyrometer filament should always be parallel to the background filament. This, of course, requires that the pyrometer filament be much smaller than the image of the background filament used as a standard.

A ribbon tungsten filament with some mark to indicate the exact spot sighted upon is sometimes used as a standard background against which to calibrate a pyrometer filament. The ribbon filament does not require as much magnification as the wire filament. A commercial form of the disappearing-filament pyrometer which has a small magnification can be calibrated, using such a ribbon filament, providing an extra lens is used between it and the pyrometer so as to give a large image of the filament. If a lens is used corrections must be made for its transmission, or the background lamp must be calibrated by means of the standard pyrometer with the lens before the lamp. The transmission of a lens is measured in much the same manner as is the transmission of a piece of absorbing or other glass. The method generally employed is to form an image with the lens whose transmission is being measured and then, taking care to see that the lens is not limiting the beam, to measure the brightness of this image and compare this brightness with that of the standard source as observed directly.

If transmissions are measured with the pyrometer, it is necessary to have it calibrated for relative brightness rather than for temperature. If a number of calibrated rotating sectors are available, this is very easily done. It is only necessary to find the currents through the pyrometer filament for apparent brightness matches against a standard source when the different sectors are used and plot a curve between relative brightness as given by the transmission of the sectors and the current.

If it is not possible to do this in an industrial plant, such work can always be done in a standardizing laboratory. From the transmission of the lens thus determined, the correction to the temperature can be calculated by means of equation (1), where in this case R is the transmission of the lens.

A ribbon-filament lamp and lens combination has been used to calibrate a Wanner type of optical pyrometer. In this case, the image of the filament was focused on the slit of the pyrometer and readings made by obtaining the relation between the scale of the pyrometer and the temperature of the ribbon filament, corrected, of course, for the transmission of the lens.

Approximate Values by Interpolation

If a rotating sector or an absorbing glass of known transmission is used between the source being investigated and a calibrated pyrometer lamp, the calibration of this pyrometer with the sector or absorbing glass can be extended above the standard black body. In this case, the temperature is to be calculated from the temperature corresponding to the current through the pyrometer filament and the transmission of the sector or absorbing glass used by means of equation (1) above, excepting that for this computation, R is the reciprocal of the transmission of the sector or glass and then T_2 will come out greater than T_1. A very convenient method is to work out such extrapolated temperatures for the various sectors, as shown in Table II.

In this table are given a series of extrapolated temperatures using different sectored disks. In column 1

[2] *Gen. Elec. Rev.*, vol. 20, p. 749 (1917).
[3] Worthing, *Astrophys. Jour.*, vol. 36, p. 345 (1912).

are given the initial temperatures, that is, the ones that would correspond to the pyrometer reading without any sector, and in the other columns are given the extrapolated temperatures corresponding to the same pyrometer readings when the sector whose transmission is given at the head of the column is used between the pyrometer lamp and the source studied. When these extrapolated temperatures are plotted against the initial temperatures the extrapolated temperatures corresponding to any pyrometer reading can be obtained. A like set of curves can be made for a series of absorbing glasses of known transmission. Such curves can then be employed with any pyrometer having the same red glass, providing the same sectors or absorbing glasses are used.

TABLE II.

Initial temperature	Extrapolated temperatures, using red glass, for various sectors with transmissions as given. $C_2 = 14{,}350\mu$ deg. Transmission of Sectors.

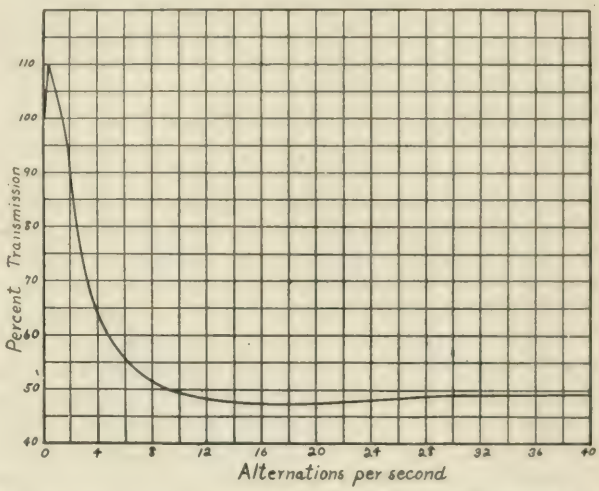
Sectors and Absorbing Glasses

A few words might well be said concerning the sectors or absorbing glasses that are used in calibrating the pyrometer or in extending the scale beyond that for which the pyrometer is calibrated directly. The list of sectors (about 35 cm. in diameter) given in Table I have been found satisfactory for temperature work The transmission of the sectors or absorbing glasses must be known to somewhat better than 1 per cent for accurate work. The sector must rotate at such a speed that no flicker is noticeable. To accomplish this, the alternations must be at least 30 to 40 per sec. This is for the condition where the open and closed spaces of the sector are about equal in size. If there is a very great difference between the open and closed parts of the sector, as for instance in the case of the 2-deg. sector with two 1-deg. openings, the speed must be higher. If the motor available will not rotate the sectors fast enough when there is but one opening and one closed part, it is often a great help to make more open spaces. A good plan is to have six openings, which will reduce the necessary speed considerably. For a sector as small as two having a 1-deg. opening this is impossible without making the sector too large, because if the sector opening is too small there is danger of an error due to diffraction. In this case, with a sector the size of the one here used, it is necessary to have a motor that will rotate it something like 3,500 r.p.m.

In the accompanying figure are shown the values found for the transmission of a 180-deg. sector as a function of the speed in alternations per second. This transmission was measured with the optical pyrometer. It can be seen, as shown in the curve, that the value found is constant and equal to the transmission of the sector for alternations above about 30 per sec., but below that the transmission at first becomes smaller and then larger, and an apparent transmission of over 100 per cent is obtained for a speed of alternations of about 1 per sec. The transmission, of course, approximates 100 per cent for zero speed.

The values found for the transmission for speeds corresponding to alternations between 10 and 30 per sec. is due to a flicker which bothers the observer. It might be that another observer would get slightly different values for the transmission for such speeds. For speeds slower than 10 alternations per sec. the observer attempts to make settings when the open part of the sector is passing before the opening. There is a very great flicker and settings are attempted using only the bright part. The value found for extremely low speeds is due to the apparent over-shooting of the brightness of the source when viewed only for the short time as compared with the pyrometer filament, that always has about the same brightness.

If the sector has a long opening measured in the direction of the radius, care must be taken to always use about the same part of this opening. This is to avoid error due to the fact that the radial sides of the openings may not be straight or may not be in a radial direction.



TRANSMISSION OF 180-DEG. SECTOR (TRANSMISSION 0.492) AS A FUNCTION OF THE SPEED OF ROTATION IN ALTERNATIONS PER SECOND

Absorbing glasses are not, in general, neutral tint. However, this is not necessary. All that is needed is to have a glass whose spectral transmission is nearly enough independent of the wave length to enable different observers to make brightness comparisons with very nearly the same results. The absorbing glass must be mounted in such a manner that the exact part that was calibrated is always used. This is because even the best absorbing glass is apt to vary in its transmission from point to point. Mounting must also be such that the beam of light will always make the same angle with the absorbing glass. Most absorbing glasses, when used with the red glass of the pyrometer, have a transmission that depends upon the distribution of energy, that is, the temperature of the source. This, of course, must be known and allowed for in accurate work.

Cleveland, Ohio.

Export Embargo on Gum Copal in Sierra Leone

Consul W. J. Yerby has reported from Dakar, Senegal, that an order in council of April 26, 1920, prohibits the exportation of gum copal from that colony for a period of three years beginning Sept. 30, 1920.

Synopsis of Recent Chemical & Metallurgical Literature

Magnesite Refractories.—From the scattered articles appearing in the technical press of the last generation and a survey of the salient facts in the entire field pertaining to the occurrence, preparation and properties of magnesite for refractory use V. SPOTTS MACDOWELL of the Harbison-Walker Refractories Co. and RAYMOND M. HOWE of the Mellon Institute have prepared an exhaustive paper on the subject which appears in the March, 1920, issue of the *Journal* of the American Ceramic Society. The development of this refractory began as early as 1860 in Europe for use in the bessemer process and has progressed to the production of 131,924 tons of calcined material in 1918. Iron oxide is now used to secure the proper sintering and bonding properties and is incorporated at extremely high temperatures.

The principal crystalline deposits are found in Austria-Hungary, Washington State and the Province of Quebec. Cryptocrystalline or amorphous beds occur in Greece, California, India, the Transvaal, Venezuela and the Cedros Islands, off the coast of Mexico.

The preparation in Europe and California involves largely burning in bottle-shaped kilns, while Canadian and Washington producers employ the rotary type. In the small ware magnesia crucibles are sometimes made by machining the brick. Linings for graphite laboratory crucibles used in preparing ferro-alloys are molded in place by tamping calcined magnesia around a wooden core. The core is removed, the lining dried, and burned in a carbon resistance furnace to a temperature above 1,755 deg. C.

Magnesia brick is commonly made from a dead-burned magnesite containing 4.5 to 8 per cent Fe_2O_3. Bonding material is not ordinarily used in American practice. The magnesite is mixed in a wet pan with a small amount of water and moldings are made in power press. After drying in tunnel driers rectangular down-draft kilns are used for burning and the bricks are then cooled slowly to avoid cracking.

The properties of the brick are given in this paper as to color, texture, specific heat, microscopic structure, chemical composition, crushing strength, thermal expansion, hydration and slaking.

Carbon acts on magnesia at high temperatures to cause shrinkage fitting and a black soot consisting of an intimate mixture of magnesia and carbon deposits on the walls of the electric furnace. The reaction is generally thought to occur as follows:

$$\underset{\text{solid}}{MgO} + \underset{\text{solid}}{C} = \underset{\text{vapor}}{Mg} + \underset{\text{vapor}}{CO}$$

The vapors have a reversible reaction on the cool walls of the furnace to make this sooty mixture. The temperature of the reaction varies from 1,450 to 2,030 deg. C. as recorded by different observers.

The authors conclude with the following: "The field for investigation of the properties of dead-burned magnesite and magnesia brick, and of the possibilities of improving their commercial value, offers a number of attractive problems. The influence of texture and composition of the raw magnesite, and the effect of added impurities upon the properties of the burned product, are not thoroughly understood. How the change from amorphous magnesia to periclase crystals may be brought about most economically and completely, and the crystals bonded together to form a brick which will be strong at furnace temperatures, with minimum shrinkage and tendency to spall, are questions deserving much careful study."

A large selected bibliography of magnesite and magnesite brick dating from 1873 is appended to the paper.

Supplementing the Natural Gas Supply With Byproduct Coke-Oven Gas.—The rapid increase in the demand for natural gas, coupled with the exhaustion of wells in districts that owe an important part of their industrial development to the availability of this valuable fuel, presents a problem which already demands serious attention. At the Buffalo meeting of the Natural Gas Association, C. J. RAMSBURG pointed out the opportunities afforded by the byproduct coke industry in the way of supplementing our natural gas supply. The paper was published in full in *Gas Age*, vol. 45, p. 456; May 25, 1920.

Of the high-grade artificial gases available with present methods of manufacture, only two, coal gas and carburetted water gas, deserve serious consideration. A very important factor in the cost of carburetted water gas is the price of gas oil, and this has increased to such an extent as to make any large-scale competition of carburetted water gas with coal gas out of the question. Moreover, we are beginning to face a condition of oil shortage quite analogous to our natural gas shortage. This condition is seriously embarrassing the manufacture of carburetted water gas in many plants and has already led to the erection of a number of coal gas plants.

The gas produced by heating coal in retorts is usually referred to as coal gas, but the byproduct coke oven is capable of furnishing a high-grade gas which is just as truly coal gas as that made in the retort. Furthermore, the byproduct coke oven possesses many advantages over the gas retort for the large-scale manufacture of coal gas: The coke is of superior quality; the yields of ammonia and benzol are greater; the coal and coke are handled mechanically in relatively larger masses; the heating efficiency is greater; the life of the plant is longer. The annual consumption of coke-oven gas for domestic and industrial purposes (outside of iron and steel plants and other establishments with which the byproduct coke ovens are directly connected) is about 40,000,000,000 cu.ft.

To those who are familiar with the enormous rate at which natural gas is being produced and consumed, it might seem that any artificial source of supply must be small in comparison. However, it is estimated that the average normal consumption of coal for the manufacture of coke during the next five years will be approximately 86,000,000 net tons per year. If all of this coal were coked in byproduct ovens, we should have a gas yield of 10,500 cu.ft. per ton, or a total gas production of 900,000,000,000 cu.ft. of gas per year, which is probably a greater volume than the present annual production of natural gas. This figure represents the maximum possible gas production in connection with coke manufactured at the present average rate. We have not, however, got to the point where every ton of coke will be made in byproduct ovens.

Of the 86,000,000 tons of coal used for the manufacture of coke, it may be estimated that, during the next five-year period, 46,000,000 tons will be coked per year in byproduct ovens, with a total gas production of 480,000,000,000 cu.ft. The waste of gas from beehive ovens will continue at a rate of 420,000,000,000 cu.ft. per year.

One of the most important factors affecting the availability of coke-oven gas for use outside of the plant is the substitution of a low-grade gas for heating the ovens. Producer gas or blast-furnace gas is well adapted to this purpose, thus releasing the entire output of richer oven gas for distribution. The advantages of producer gas for heating the ovens may be summed up as follows:

First, the producers may be fed with small sized coke unsuitable for use in the blast furnaces. Here the equipment is simple and comparatively inexpensive, especially with respect to the gas-cleaning apparatus. The amount of coke required for the producers is 12 to 14 per cent of the weight of the coal charged into the ovens. This amount may readily be obtained by properly screening the oven product, leaving a high-grade, thoroughly clean coke for the use of the blast furnaces.

Second, where there is available a cheap coal, having fair coking qualities, but unsuitable for the manufacture of blast-furnace coke, such coal may be coked in some of the byproduct ovens, delivering thereby its byproducts and furnishing sufficient coke for the operation of the gas producers.

Third, where there is available cheap low-grade coal unsuitable for making blast-furnace coke, such material may be used directly in the gas producers.

Fourth, byproduct producers may be installed using any coal available. The equipment and operation of byproduct producers fits in very well with that of the byproduct coke plant, and the combination, costing much less than separate plants, offers many possibilities for increased economy and valuable returns. Heretofore, on account of coal values, the employment of byproduct gas producers has been more extensive in Europe than in America, and here, with the present appreciation of coal values, their development presents enormous possibilities.

As the demands of the natural gas industry for a supplementary supply of high-grade artificial gas outgrow the possibilities afforded by such byproduct coke plants as are operated in connection with iron and steel plants in any locality, it is certain that additional byproduct coke plants will be erected primarily to meet the needs of the natural gas industry. Much might be saved if it were possible to build the byproduct coke ovens at the coal mines, as has been the general practice in the case of beehive ovens; but this has hitherto seldom been permissible, either because the mines were located too far from the consumers of gas, or because the locations were in districts well supplied with natural gas. With diminishing natural gas supply, the peculiar relations of the natural gas industry with respect to the coal-mining regions of Pennsylvania, Ohio and West Virginia are likely to make it profitable to build byproduct coke ovens at the mines, because many coal mines supplying good coking coal are within easy reach of large natural gas distributing systems into which the coke oven gas could readily be conveyed. With a reasonable price for the gas and with proper methods of coke disposal, such plants can operate with maximum economy. The low price of land at the mines is an important item.

Progress toward the general use of gas as sole domestic fuel must necessarily be slow and depends largely on accustoming people to lower heat value standards. There can be no question that at present, from an economic standpoint, we are working on too high a level as regards the heating value of gas.

It is the opinion of many economists who have studied the problems of conservation and efficient utilization of our fuel resources that the ultimate ideal should be the conversion of all the coke into gas at the byproduct coke plant, so that the plant will supply all of its fuel product in gaseous form. It may be that we are in a transition period that will ultimately end in discontinuing entirely the use of solid fuel for most industrial and for all domestic purposes.

The proposition of gasifying all of the coke produced at the byproduct coke plants leads to the subject of mixed gases, because all of the surplus gas produced from the coke over and above the requirements of the plant for its own steam, power and heating will, in the majority of cases, be mixed with the coke-oven gas before distribution to the consumer. This subject is one of great importance. It has such a wide scope and involves so many subsidiary questions, both economic and technical, that it cannot be adequately treated within the limits of this paper. Attention will, however, be directed to a few leading points.

1. The mixed gas sold to the consumer must have such characteristics with respect to specific gravity and heating value as to meet his purposes satisfactorily without unduly increasing the investment required for his appliances.

2. The question of the rate of heating afforded by the gas is in many cases more important than the total heat units supplied. The rate of heating is, of course, a function of the flame temperature. For example, straight producer gas has been burned in cook stoves, but its flame temperature is so low that it works much too slowly to be practicable.

3. It is very questionable whether it ultimately pays to sell gas containing a large percentage of inert, incombustible constituents for wide distribution. The principle involved is much the same as in the transportation of coal containing high percentages of ash.

4. There are two generally feasible methods for the production of mixed gas at the byproduct coke plant with complete gasification of the coke, viz.:

(a) Gasification of the coke in producers using part of the producer gas to heat the ovens and the remainder to mix with the coke-oven gas. This method would produce per ton of coal over and above plant requirement, 10,500 cu.ft. coke-oven gas of 560 B.t.u. and 75,600 cu.ft. of producer gas of 130 B.t.u., making 86,100 cu.ft. mixed gas of 183 B.t.u.

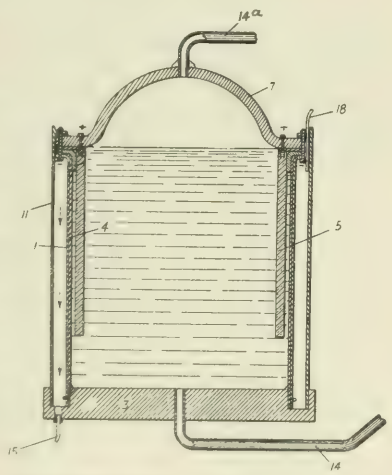
(b) Part of the coke is gasified in producers making sufficient gas to heat the ovens. The remainder of the coke is put into water gas generators and its carbon converted into blue water gas, which is mixed with the coke-oven gas. This method will produce per ton of coal 10,500 cu.ft. coke-oven gas of 560 B.t.u. and 22,600 cu.ft. blue water gas of 300 B.t.u., making 33,100 cu.ft. mixed gas of 383 B.t.u.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Compressed Ethylene. — Ethylene can be directly compressed to a high pressure, far in excess of that to which acetylene can be safely compressed, and can be stored in cylinders or containers without the use of an absorbent filling and solvent, and without the danger and disadvantages incident to the compression and storage of acetylene. The entire space of the cylinder can, accordingly, be filled with the compressed ethylene. Moreover, since the ethylene is present in a gaseous, rather than a "dissolved" or liquid state, the entire content of the cylinder can be made available, even in the coldest weather, without objectionable lowering of temperature due to evaporation. A cylinder having a cubical capacity of about 0.777 cu. ft. (commonly called a 100 cu.ft. hydrogen or oxygen cylinder) can be safely charged with from 150 to 200 cu.ft. of ethylene. Expressed in terms of cu.ft. ethylene per cu.ft. cylinder capacity, it is easily possible to charge 200 to 250 cu.ft. of ethylene per cu.ft., whereas with hydrogen and oxygen the cylinders contain only about 130 cu.ft. per cu.ft. (1,339,431; ARTHUR A. BACKHAUS, of Baltimore, Md., assignor to U. S. Industrial Alcohol Co.; May 11, 1920.)

Electrolytic Chlorine Cell.—The apparatus consists of: A perforated cylindrical iron cathode, 1, resting in an annular channel in the base member, 3; a cylindrical diaphragm, 4, inside of the cathode; a cylindrical graphite anode, 5; an exterior casing, 11; a dome, 7, bolted to the body of the cell in such a manner as to insulate the anode from the cathode and make the anode and cathode compartments gas tight. Sodium chloride solution enters the cell at the bottom through pipe 14. The products of electrolysis — chlorine, sodium hydroxide solution and hydrogen — are removed through 14a, 15 and 18 respectively. The dome-shaped head permits the level of the electrolyte to rise as the porosity of the diaphragm decreases, thereby insuring an even flow of liquor through the diaphragm at all times irrespective of the degree of porosity of the latter. The dome also serves as a conductor to the graphite anode, doing away with the copper busbar commonly used. (1,342,336; PAUL MCDORMAN, of Niagara Falls, N. Y., assignor to the Electro Chemical Co.; June 1, 1920.)



ELECTROLYTIC CHLORINE CELL

Electrolytic Hypochlorite Cell. — In hypochlorite cells where the hypochlorite is formed near the electrodes, there is a reduction in efficiency due to secondary reactions. At the cathode some of the OCl ions are reduced to Cl ions, while at the anode ClO_3 ions are formed by oxidation. JOHN GERSTLE, of Dayton, Ohio, has designed a cell in which the chlorine and sodium hydroxide are generated separately and then mixed in baffled chambers so that the hypochlorite formed does not come into contact with the electrodes. (1,342,378; assigned to Electro Chemical Co.; June 1, 1920.)

Sulphuric Acid Concentration. — Incrustations of sulphates which form in concentrating sulphuric acid in the cascade system may be removed by passing weak and strong acid through the cascade alternately. The weak chamber acid removes the incrustation left by the strong acid. (1,340,290; JOHN PATTEN, of Baltimore, Md., assignor of one-half to Samuel M. Shoemaker, of Eccleston, Md.; May 18, 1920.)

Sulphuric Acid from Sulphur Dioxide and Selenium Dioxide.—Selenious acid (prepared by treating selenium dioxide with water) will oxidize sulphur dioxide to sulphuric acid according to the equation:

$$SeO_2 + 2H_2O + 2SO_2 \leftrightharpoons Se + 2H_2SO_4$$

Complete elimination of the SeO_2 is assured by repeated treatment with SO_2 at about two atmospheres pressure. The precipitate of selenium is removed by filtration. It may be roasted to form the dioxide again. Tellurium dioxide may be used in the same manner. (1,341,462; PAUL HAESELER, of New York, assignor to the Liberty Laboratories, Inc.; May 25, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Gallic Acid.—Gallic acid is obtained by heating tannin with an amount of a metallic compound sufficient to effect a substitution of the hydrogen atoms of the carboxyl and hydroxyl groups formed on hydrolysis, and then decomposing the resulting gallate with an acid. An excess of the metallic compound is preferably employed, in order to coagulate the albuminous material. The metallic compounds referred to are the hydroxides, oxides and weak acid salts (e.g., carbonates and acetates) of the alkali and alkaline-earth metals, magnesium, lead, copper and zinc. (Br. Pat. 139,419—1919. NITRITFABRIK AKT. GES., Kopenick, Germany, April 28, 1920.)

Carbazol. — Carbazol is purified and obtained in well-defined crystals by slow dilution of its solution in concentrated sulphuric acid. This may be effected by exposing the solution to the atmosphere or other moist gas, with or without agitation, or by blowing air or other moist gas through the solution. The solution may first be diluted rapidly to a degree short of precipitation and then diluted slowly as described above. (Br. Pat. 139,441—1919. SOUTH METROPOLITAN GAS Co. and W. KIRBY, London, April 28, 1920.)

Treating Vegetable Fibers.—Vegetable fibers in the raw state, or bleached, or mercerized, and in the mass or in the state of laps, cops, card-ends, twistings, etc., or yarns or fabrics, are treated to impart to them the character of wool by steeping them at ordinary temperatures in nitric acid, preferably at a concentration of not less than 65 per cent, and then squeezing and washing the fibers. (Br. Pat. 136,568—1919, 136,569—1919. SOC. GILLET ET FILS, Lyons, France, Feb. 11, 1919.)

Current Events
in the Chemical and Metallurgical Industries

American Ceramic Society to Hold Summer Meeting at Chicago

The regular summer meeting of the American Ceramic Society will be held at the La Salle Hotel in Chicago Aug. 16, 17 and 18. Aside from a short business meeting the tentative program as outlined by the committee of the Chicago Section will be as follows:

MONDAY, AUG. 16

The members will assemble in the rooms provided at the La Salle Hotel about noon and will be taken by automobile to the plant of the Northwestern Terra Cotta Co. After an inspection of this plant the Lindsay Light Co.'s manufacturing plant will be visited. This company is engaged in the reduction of rare earths to be used in the manufacture of lamp mantles which the company produces, together with some of the rare metal compounds such as thorium, cerium, lanthanum and other nitrates derived from monazite sands.

TUESDAY, AUG. 17

Visit to the plant of the Coomley Manufacturing Co., maker of enamelware; the plant of the Burke Brick Co., manufacturer of common brick, and the Western Electric Co. plant.

WEDNESDAY, AUG. 18

A trip will be made to the manufacturing plants in the vicinity of Waukegan and North Chicago, including the Fansteel Products Co., manufacturer of pure tungsten, molybdenum and rare metals.

On Monday evening the informal dinner will be held at the La Salle Hotel, and on Tuesday and Wednesday evenings the visitors will be left to their own devices.

The detailed program will be published later.

Chemical Warfare Service on a Peace Basis

By July 1 the personnel of the Chemical Warfare Service will have been reduced by 50 per cent. This is by way of a general reduction from a war footing to a peace basis. The peace nucleus of the Chemical Warfare Service, however, expects to be a very active branch of the War Department. It has $4,000,000 at its disposition to use in its work during the next fiscal year. The manufacture of the latest type of the American gas mask is now reaching quantity production. The first mask of this type was completed June 4. Sufficient masks must be manufactured to equip the entire Army and National Guard. The new mask is described as a real fighting mask. It is comfortable to wear, permits clear vision and can be kept on continually, without particular inconvenience, as long as the wearer can go without food and drink.

Formal designation of the chief of the Chemical Warfare Service, who is to have the rank of Brigadier General, will take place shortly after July 1, it is believed, when the Chief of Staff will have returned from France. It is taken for granted that Colonel Amos A. Fries, who has been at the head of the service since the resignation of General Sibert, will be elevated again to the rank of general and assigned to the direction of the service in its permanent capacity as a separate branch of the War Department.

The Chemical Warfare Service, according to the new statute, is to have 100 officers. Only six of the officers now on duty with the Service hold permanent commissions, consequently ninety-four officers must be commissioned or detailed for duty with the Chemical Warfare Service. At present a large number of those interested in obtaining permanent commissions are taking the necessary examinations. It is the policy of Colonel Fries that 25 per cent of the officers be chemists. The principal duties of the remainder are of a military, constructional and manufacturing character, but even in those cases some chemical education is regarded as desirable.

In this connection, it may be remarked that the Chemical Warfare Service to date has been conducted almost entirely by temporary officers. They are responsible for much of the success which has been made by the Service. When the armistice was signed only 1 per cent of the officers in the Chemical Warfare Service were Regular Army men. Most of those were in the minor grades.

Resolutions Passed by the Natural Gas Conservation Conference

Definite progress was made in the Natural Gas Conservation Conference at the Department of the Interior on June 11, when tentative resolutions proposed by the National Committee on Natural Gas Conservation were approved. The conference included representatives of the Governors and Public Service Commissions of a number of the important natural gas producing and using states.

Some of the resolutions which were thus approved relate to industrial chemical activity very directly. Carbon black production, casinghead-gas recovery, and the substitution of natural gas for gas oil in making carburetted water gas are of special concern. The text of these resolutions is as follows:

> That the use of high B.t.u. natural gas instead of gas oil in carburetting manufactured gas, where same is made to supplement the decline in production of natural gas, be encouraged because the use of gas oil at 73c. per gal. has the equivalent B.t.u. value of 108 cu.ft. of natural gas at 1,100 B.t.u., giving the gas a comparative value of 75c. per 1,000 cu.ft. and thereby helping conservation.
>
> That carbon black be made when gas is produced in isolated sections with no present or reasonably prospective market for gas being produced, when gasoline has been extracted and when practical and modern and improved methods are used.
>
> That in the interests of good conservation and good service—wherever expedient—all gasoline that can be commercially separated from natural gas shall be so separated before the gas is started for market.
>
> That the Bureau of Mines be asked to turn over to this committee all data it may have on the carbon black industry with the view and purpose of helping this com-

mittee to determine what part of natural gas now used to manufacture carbon black could be diverted into public utility lines.

It is expected that a conference of state representatives of Pennsylvania, West Virginia and Ohio will meet soon in Pittsburgh to formulate a policy with respect to the gas exported from West Virginia into the two other states. It is hoped that similar measures mutually satisfactory to exporting and importing states will be arranged for Oklahoma, Kansas and Missouri, etc. It is also expected that regulations similar to the resolutions adopted by the conference will be made legally binding by some of the state legislatures. Especially is this action expected in Louisiana, where the Conservation Commissioner plans to introduce such legislation.

Federal Officials Organize

More than a hundred members of the Government service who are in responsible administrative and technical positions met on June 17 and perfected a tentative organization which is to be known as "The Federal Club." The purpose of the organization is by the interchange of views, and, where appropriate, by joint action to care for many of the general problems of the service which are common to several departments. Franklin D. Roosevelt, Assistant Secretary of the Navy, is the chairman of the temporary body, and Dr. E. B. Rosa, chief physicist of the Bureau of Standards, is chairman of the committee on organization and constitution. Some of the problems which have been suggested for the action of the club are classification and salaries of the technical services of the Government, and budget matters as affecting the executives of the various Bureaus.

New Zinc Oxide Company Formed at Leadville, Col.

The Western Zinc Oxide Co. has been recently formed at Leadville, Col., by a consolidation of the Western Zinc Concentrating Co. and the Leadville Zinc Co. The new company is controlled by J. F. McDonald, of Leadville, Charles J. Walker, of St. Louis, and other St. Louis capitalists. They are connected with the Downtown Mines Co.

A block of sixteen furnaces, a new pipe line, bag house and complete mining equipment is being added to the present plant. When the new unit is completed thirty-four furnaces will be in daily operation, giving the plant a capacity of about 100 tons of zinc oxide daily.

The new furnace building will be 120 ft. long by 44 ft. wide, and the bag house 700 ft. by 44 ft. Wetherill type furnaces are being built. It is planned to have the new unit in operation by Aug. 1. Charles H. Collins is president and manager of the new company.

Allocation of German Dyes

The War Trade Board Section of the Department of State announces that it is now prepared to grant allocation certificates providing for the importation of German dyes in amounts sufficient to supply the immediate requirements of individual consumers of the United States for a six months' period.

Before an allocation certificate providing for the issuance of an import license will be granted by the War Trade Board Section the consumer must file an application with the War Trade Board Section on an official form provided for that purpose.

Applicants are advised to estimate their requirements as accurately as possible, as all estimates will be carefully scrutinized. Any applications which appear to be excessive will not be acted upon until the matter has been investigated and found satisfactory to the War Trade Board Section.

Importations will be controlled by rules and regulations similar to those which governed the previous allocations. Licenses to import will be issued only when the dyes applied for are not obtainable from domestic sources on reasonable terms as to price, quality and delivery.

New Bodies Represented on the American Engineering Standards Committee

Five additional bodies have been admitted to representation on the main committee of the American Engineering Standards Committee. They are:

Electrical Manufacturers Council: Electric Power Club, Associated Manufacturers of Electrical Supplies, Electrical Manufacturers Club.

Fire Protection Group: National Fire Protection Association, National Board of Fire Underwriters, Associated Factory Mutual Fire Insurance Companies, Underwriters Laboratories.

National Electric Light Association.

National Safety Council.

Society of Automotive Engineers.

These, with the five engineering societies who founded the Committee and the three Government departments, added later (Commerce, Navy and War), make a total of thirteen organizations having representation on the main committee.

The constitution of the A.E.S.C. provides for representation of "groups of organizations." It is the policy of the committee to encourage representation by groups in such manner that a group shall represent substantially the entire field of a particular industry in order that it may "be of national scope." In the opinion of the committee the group plan makes both for efficiency in standardization work and for effectiveness of representation. The groups are autonomous, such matters as the apportionment of representatives and the allotment of fees among the constituent bodies resting wholly with the group.

Two of the new bodies have already designated their representatives as follows:

Electrical Manufacturers Council: Le Roy Clark, A. H. Moore, C. E. Skinner.

National Safety Council: C. P. Tolman, chairman, Manufacturing Committee; Albert W. Whitney, general manager, National Workmen's Compensation Service Bureau; Sidney J. Williams, secretary and chief engineer.

Storage of Poisonous Gases

Poisonous gases store very much better than had been expected. Recently completed tests by the Chemical Warfare Service show that all gases used in warfare except mustard and sulphur monochloride can be stored for long periods without deterioration. Even in the case of mustard gas, the deterioration is not great. All of the gases which were the subject of these tests had been in storage at least twenty months. Due to the corrosive properties of chlorine, some difficulty has been found in preventing its escape from containers after long periods of storing.

Uses of Bentonite Clay

Bontonite clay is a non-metallic mineral of commercial importance used in the manufacture of soap and antiphlogistine and the purification of water. It is produced principally in Wyoming and is marketed to the extent of a few hundred tons per year. Detailed information can be found in the United States Geological Survey Bulletins Nos. 260, 285 and 365; also in U. S. Geological Survey Professional Paper No. 153.

Mantle Lights Used in Canton

Many concerns in Canton use mantle lights, often burning gasoline or a low grade of kerosene. Those now on the market sell at from 30c. to 65c. each and come principally from the United States and England.

Personal

Prof. S. A. ARRHENIUS of Nobel Institute, Stockholm, Sweden, was awarded the Frank Medal by the Franklin Institute, May 19, 1920. Dr. Allerton S. Cushman, in connection with the presentation, read a paper by Prof. Arrhenius entitled "The World's Energy Supply."

Dr. JAMES BROWN, formerly research chemist for Zinsser & Co., Hastings-on-Hudson, N. Y., has accepted a similar position with the Calco Chemical Co., Bound Brook, N. J.

GEORGE A. CHRITTON spoke before the Chicago Chemists' Club weekly luncheon on trade marks, unfair trade and the law.

H. P. FISHBURN, formerly with the University of Idaho, is now chief chemist at the Casper, Wyo., works of the Standard Oil Co. of Indiana.

Dr. LOUIS J. GILLESPIE, professor of physical chemistry at Syracuse University, who was formerly with the Department of Agriculture, Washington, D. C., has resigned to go to the Massachusetts Institute of Technology as assistant professor on physicochemical research in the research laboratories of physical chemistry.

HOWARD A. HORNER, formerly metallurgist of the American Metallurgical Corporation, Philadelphia, is now with the Frick Co. of Waynesboro, Pa.

ROBERT M. KEENEY of Denver was East recently on a business trip.

FRANKLIN K. LANE, formerly Secretary of the Interior, received the honorary degree of Doctor of Laws at the commencement exercises at Williams College June 21.

OLIVER LOUD, formerly plant chemist of the citrus byproduct factory of the California Fruit Growers Exchange, Corona, Cal., and during the war assistant in physiological research with the Chemical Warfare Service, is now engaged as chemist at the refinery of the Standard Oil Co. of California, Richmond, Cal.

A. M. MUCKENFUS has resigned as professor of organic and industrial chemistry and director of that sub-department at Emory University, Atlanta, Ga., to accept the position of research chemist with the Roessler & Hasslacher Chemical Co., Perth Amboy, N. J.

Sir W. J. POPE is to be nominated president of the Society of Chemical Industry, London, at the meeting to be held at Armstrong College, Newcastle-on-Tyne, July 13, 1920.

PAUL C. SKINNER, general manager of the Denver plant of the General Chemical Co., has been in Chicago recently on business.

HARRY A. TIEMANN, Colorado State Superintendent of Industrial Education, delivered an address recently before the Colorado Society of Engineers.

Current Market Reports

The Non-Ferrous Metal Market

New York, June 28, 1920.—The leading producers quote 19c. for all copper deliveries up to August, with the outside market at 18c. for spot. Platinum and palladium have advanced $5. Other prices are firm.

	Cents per Lb.
Copper, electrolytic	18.00@19.00
Aluminum, 98 to 99 per cent	33.00
Antimony, wholesale lots	8.00
Nickel, ordinary	46.00
Nickel, electrolytic	45.00
Tin, Straits, spot	48.50
Lead, New York, spot	8.00
Lead, E. St. Louis, spot	7.75
Zinc, spot, New York	7.75
Zinc, spot, E. St. Louis	7.45

OTHER METALS

Silver (June 24)	oz.	$0.99¾
Cadmium	lb.	1.40@1.50
Bismuth, (500 lb. lots)	lb.	2.70@3.00
Cobalt	lb.	2.50@3.00
Magnesium (f.o.b. Niagara Falls)	lb.	1.60@1.85
Platinum	oz.	80@90
Iridium	oz.	300
Palladium	oz.	75@85
Mercury	75 lb.	90

Lead, heavy	7.00@7.25
Zinc, scrap	5.00@5.25

The Iron and Steel Market

Pittsburgh, June 25, 1920.

The rail transportation situation is growing no better, and even the more sanguine in the iron and steel industry do not look for any decided improvement until some distinctly new developments occur. Announcement of the findings of the Railroad Labor Board, expected now in two or three weeks, might help.

While there is no noticeable improvement in the shipment of pig iron or of finished steel, there is a distinct improvement in the movement of coal, at least from the Pittsburgh district, this arising without doubt from the coal car preference order of the Interstate Commerce Commission, effective at the beginning of last week. Connellsville coke operators complain that the order will result in the withdrawal of cars from the coke movement to put into the coal movement, but any such change if made would probably be to the advantage of the iron industry as a whole, through there being a better movement of coal to byproduct coke ovens.

Production of pig iron and steel ingots is at about the same rate as a week or a fortnight ago, the rate being not far from that of last March, when the highest rate was attained since October, 1918. In view of rather light demand in some quarters it is doubtful whether the total of demand is equal to the present rate of production. There is very little railroad demand and there is no large amount of steel being required for large works of construction. The Bridge Builders' and Structural Society reported May book-

ings of fabricated steel contracts equal to 61½ per cent of a month's capacity, against 68 per cent for April and 83½ per cent for March. Not a few manufacturing consumers are operating at well under capacity, partly from lack of orders, and even the automobile industry has slowed down, though that is of less consequence than would be assumed from the large part the automobile industry played in advancing the market early in the year, since at best the industry could not fill up more than say 6 or 7 per cent of the steel industry's capacity. An easier market for steel in the not distant future is therefore in prospect, unless there should be a large curtailment in output by labor disturbances or from fear of labor disturbances.

Market Prices

Connellsville coke continues very strong, with prices for spot shipment up 50c. to $1 in the week, furnace coke being $15.50@$16 and foundry coke $16@$17 per net ton at ovens. Some operators are quoting $12 as a flat price for furnace coke for second half, a price furnaces are unwilling to pay. There are also quotations at a ratio of 4 to 1 against basic pig iron at valley furnaces, which at the present pig iron market of $44 would mean $11 for the coke. Some coke operators expect pig iron to advance, while furnacemen who have bought on the 4 to 1 ratio probably expect it to decline.

A sale of 2,000 tons of bessemer pig iron at $44, valley, establishes the minimum of the market at this figure, an advance of $1, while small lots have gone at $45. Basic sold in one 2,000-ton lot at least at $44, an advance of 50c. Foundry remains at $45, valley. The market is made only by early deliveries, there being no disposition on the part of consumers to buy for the remainder of the year, and thus the technical position is one that readily admits of advances or declines in future. The present market, being made on prompt lots at a time when deliveries are difficult, is not much of a criterion.

A sale of over 5,000 tons of open-hearth sheet bars has been made at $75, which would indicate a continuance of the very strong market, but there were attendant circumstances suggesting that the buyer had some ulterior motives in making the purchase. A sale of a fair tonnage of 3 x 3-in. billets is reported at $67.50, indicating an easier market, since standard billets have been quotable nominally at $60@$65 and small billets not long ago were regarded as worth $10 over 4 x 4-in. billets.

The plate market is easier, as prompt deliveries will hardly bring 3.50c., perhaps not over 3.25c., while not long ago very late deliveries were in demand at 3.25c. and prompt deliveries were bringing up to 4.50c. Other descriptions of finished steel have softened less, but the general trend is for prompt deliveries to bring smaller premiums than formerly, with extended deliveries held at former levels, but in less demand.

A few lots of heavy melting steel have been bought by Pittsburgh district consumers in the past week at $26.50, delivered. Nominally these transactions record an advance of 50c. in the market, but it is characteristic of the scrap market to have a certain level as "the market" and then when consumers buy they pay 50c. more. Borings have been in good demand at $18, with $18.50 now quoted, while machine shop turnings are off $1, at $14.50@$15. Cast scrap is stronger at $33@$34 and cupola sizes are stronger at $40@$41, both cases reflecting the difficulty in securing pig-iron deliveries.

Ferro-Alloys

Prompt ferromanganese has slumped, as was to be expected, the recent stiffness being due to a few consumers being short at the time, although covered for second half, and prompt is now worth but little more than the $200, delivered, which is still quoted on second half contracts. Spiegeleisen is $72.50@$75 at furnace. Electrolytic ferrosilicon is about $78@$80, delivered, for 50 per cent and $150, delivered, for 75 per cent. Bessemer ferrosilicon remains quotable at $62.50 for 10 per cent, $65.80 for 11 per cent and $69.10 for 12 per cent, f.o.b. furnaces at Jackson and New Straitsville, Ohio.

The Chemical and Allied Industrial Markets

New York, June 25, 1920.

The chemical market continues in the same weak position it occupied during the previous period, buying being confined to present requirements only and offerings being small with no assurance of early delivery. It is difficult to decide whether there has been any improvement in the rail situation with so many conflicting opinions being given by those engaged in the trade, but it is evident that there are more cars rolling and that terminal facilities are less congested than they were a few weeks ago. Succeeding *barium chloride*, which is still nominally quoted at $170@$200 per ton, *copperas* has come up in the last week or two and is commanding prices ranging between $3 and $4 per cwt. There is considerable difficulty in locating spot even at these figures and the best that producers can offer is late summer shipment. Domestic producers are standing firm at 12½@13½c. per lb. for *gray salammoniac* and 16@16½c. for the *white* grade. While it is reported English material is being imported a few cents below this price, volume of imported arrivals has not yet reached proportions that have warranted a reduction in domestic material. Improvement has been noticed in the *muriatic* supply and this material is accordingly somewhat easier at $3.10@$3.25 per cwt., although there is by no means a normal supply on hand, which is partly due to the slow arrival of material from producers' plants.

Considerable interest is being manifested in *carbon tetrachloride* and buying has been active at 12@15c. per lb. depending on the quantity and time of shipment desired. *Salt cake* has come up another notch and it is practically impossible to locate material at less than $30 per ton, and $34 seems to be the average price being asked by those holding resale material. There is some *caustic soda* offered at $6@$6.25 per cwt., but how much is obtainable at this figure it would be hard to say. It is rumored, however, that the firm making this offer has considerable supplies on hand. *Glycerine* continues at former levels, with 28c. the average price, and *sodium bicarbonate*, which is practically out of the hands of producers, who are sold out, came up to $2.45 as a low mark, against $2.25 per cwt. of the previous report.

Coal-Tar Products

The best that can be said about this market is that it is no worse than it was last week, implying no changes of real importance. The unsettled conditions which still prevail in Japan are a contributing factor to the continued dullness evident in this market. Buying is light, but offerings of the more desirable items on the list are lighter, and the trade continues to jog along with a noticeable mark of expectancy in its stride. *Naphthalene* is still off the market with resale material being offered nominally at 18c. per lb.; one large producer of this item is still making deliveries on contracts at 9c., which is in turn being offered on the open market at prevailing figures. There has been little interest displayed in *aniline* oil, which is listed around 35c. per lb., while, on the contrary, *aniline* salts have come up slightly with a low mark of 42c. per lb.

Oils

There has been no activity evidenced in this market during the period. The Japanese situation is tending to keep the market for Oriental oils quiet and while no drops of importance have occurred the only reason is that there is no material being offered and no inquiry being made. *Chinawood* oil, which has been steadily declining, is down as low as 18½@19½c. per lb., with practically no business being done. *Cottonseed* also came down and crude is offered as low as 15½c. per lb. *Summer yellow* is being bid around 18¾@19c. per lb.

St. Louis, June 21, 1920.

The demand for heavy chemicals, which has been manifested for the past few months, still continues and prices in some lines show an upward trend. Local production is practically back to normal, although producers are hampered by the slow movement of carload shipments. A recent local embargo on less than carload shipments, caused by a strike of the transfer companies' employees, has held up all

shipments to and from the East. This strike is now settled and the embargo should be lifted shortly.

Sulphuric Acid—The demand for sulphuric acid continues good and prices are unchanged. The 60 deg. grade is quoted at $15@$16 per ton in carload lots and the 66 deg. grade at $22 per ton. The price of oleum is unchanged at $27.50 per ton.

Muriatic Acid—The demand for this chemical is heavy and local producers report supply practically all sold up. The 18 deg. is quoted in carload lots at $25 per ton and $2 to $2.25 per 100 lb. in carboys. This is an advance of $4 per ton in the past two weeks.

Nitric Acid—Supply plentiful and prices unchanged. Quoted in carload lots at $7 per cwt. for 36 deg. grade, $8 for 38 deg., $9 for 40 deg. and $10 for 42 deg.

Sodium-Bisulphate—Demand is heavy and the supply limited. Quoted at $6 per ton. This is an advance of $2 per ton during the past two weeks.

Phenol—The supply of this chemical is plentiful and demand continues good. Quotation unchanged at 12c. per lb. in quantities of 15 tons or over.

Zinc Chloride—Price unchanged at $3.50 to $3.75 per cwt.

Zinc Oxide—Local supplies are very low and producers quoting 10c. per lb., in large lots, for third quarter delivery.

Chicago, June 23, 1920.

The very gradual return to normal trade conditions in the chemical market continues, although it is so gradual as to cause the general appearance to remain almost the same from week to week. Such price changes as have been noted have, with a few exceptions, been downward and the whole trade seems to be quietly and calmly awaiting developments.

As a unit, freight conditions are improved. Plenty of individuals can be found who will assert the contrary, but these are interests whose sources of supply happen to be in points still embargoed, or whose rolling stock requirement is such that they have particular difficulty in securing cars.

Heavy Chemicals

Alcohol and its derivatives remain the headliners so far as demand is concerned. Today's quotation on methyl grade, 95 per cent, is $3.65 per gal. in barrels, when obtainable. Dye, celluloid and similar manufacturers whose requirements for wood alcohol is absolute are being supplied after a fashion, but all consumers who can possibly use *denatured* are being forced to the slower acting product. This is in fair supply and can be had at $1.09@$1.11 per gal. *Ethyl* grade is in better supply than for some time in the past and is quoted in single barrels at $5.57½ per gal. and 5c. less in 5-bbl. lots. The alcohol condition is subject to steady improvement, as factories handicapped by their inability to secure adequate supplies of molasses are being converted to corn.

Formaldehyde is in about the same condition it has occupied for the past two months so far as supply is concerned, but apathetic buying has forced the price down to 53c. per lb. in barrels. Trade needs greatly exceed visible supply, but this is a condition which, with the opening of several new producing plants, will be gradually overcome. There is apparently nothing to prevent lower prices on this commodity in the near future. The previously noted strong tone to *glycerine* continues, present quotation on c.p. grade being 28c. per lb. in drums. Manufacturers report less transportation trouble recently but shipments are still uncertain.

In general, *alkali* products are off fractionally. The main trouble is in the difficulty of shipping goods from the factory, producers reporting variously a car shortage of from 40 per cent to 90 per cent of their requirement. The trade, knowing that local supply is bound to be easier some time, and probably soon, are reluctant to pay high prices. Today *soda ash* is quoted on contract at 3½c. per lb. and for immediate delivery out of stock at 3¾c. These figures represent a quarter cent decline. *Caustic soda*, at 6@6½c. per lb., is also off ¼c. *Sal soda* remains unchanged at $1.60@$1.65 per cwt., the concentrated being offered at $3 per cwt. *Bleaching powder* is up sharply, 7c. per lb. being asked for delivery from stock and but little to be had at any price.

Blue vitriol has been subject to frequent fluctuation with a range of only about ¼c. Today's quotation on the large crystals in carloads is 8¼c. *Aqua ammonia*, on contracts, remains unchanged, and spots have been unable to retain their previous high mark, being quoted now at 9½@10c. Short supply has forced spot quotation on *copperas* up to 4c. per lb. and producers are not able to supply the demand. *Soda nitrite* is sharply off, offers being made in the neighborhood of 20c. per lb. Available stocks are being reduced and further fluctuation is to be expected. Some interest has been shown in *carbon tetrachloride*, with spots occasionally offered below the factory price. Quotations have ranged all the way from 11@12¾c. per lb. and the market remains uncertain. *Salt cake* is up, spots bringing $40 a ton and even more.

Coal-Tar Products

The word dull describes the coal-tar market in all its factors. Because the demand for *benzol* is more pressing than for other items of the line its shortage is most obvious. Difficulty in shipping the goods is the principal obstacle, and this is not so pronounced as in the recent past. Today's receipts are offered at 28c. per gal. in cars. *Toluol* is almost as scarce and is likewise held at 28c. *Cresol* has shown an upward tendency, recent offerings being around 17c., but demand is showing a decided falling off.

Aniline oil and *aniline salt* have reacted from their high marks of May and are now offered at 33@35c. and 37@40c. per lb. respectively. Supplies remain very short, but users seem unwilling to pay the price in the face of increasing volume of supply coming from the producer. Former quotations on *naphthaline* of 16c. per lb. on balls and 15c. on flakes hold good. Supply is limited in the face of an active demand. Coal-tar acids remain practically unchanged in price with the exception of *picric* which is up to 29@30c. per lb., and has become hard to locate even at that figure, and *salicylic* which has been offered as low as 48c. The entire coal-tar line is subject to frequent fluctuation which denies a healthy tone to the market.

Vegetable Oils

The oils, for some time the weakest of the chemical lines, show further reductions and increased lack of interest. *Linseed oil* alone is practically holding its own, $2.02 per gal. being the current quotation on the raw product in barrels out of local stocks, and $1.65@$1.70 ruling on carload lots. Varying guesses on the incoming crop of flax seed have a tendency to discourage active buying and a drop in price is freely predicted in some quarters.

Oriental oils, already weakened by the Japanese financial crisis, were further affected by the recent failure of a large brokerage concern on the Coast. It is rumored that this will precipitate large stocks of various oils on the market for immediate sale. Consumers are inclined to be cautious in buying for the added reason that, in many cases, they are unable to effect shipment of their finished products. This combination of circumstances has forced prices down to a new level. *Manila coconut oil* is quoted in sellers' tanks on the Coast at 16½@16¾c. per lb., the same grade going for 16@16½c. in barrels f.o.b. Chicago. Actual transactions are few and some were at an even lower figure. *Soya bean oil* in tanks, f.o.b. Coast, is 12@12½c., with the refined, deodorized grade bringing 16@16½c. from local stocks in barrels.

Nominal quotation on *corn oil*, prime, in tanks, is 14¾@15c., with practically none changing hands. *Cottonseed oil* is equally quiet, car quotations being, on crude around 14c. and on prime summer yellow, 17c. Cash offers would probably entice lower figures.

Flotation Oils—Naval Stores

Present quotations must be regarded as purely nominal, premiums being the rule rather than the exception. *Turpentine*, pure gum spirits, is quoted at $2.18@$2.25 per gal. *Pine oil*, equally scarce and desirable, is $2 for the .933 pure steam-distilled and $1.85@$1.90 for the destructively distilled. Approximately similar conditions prevail in *rosins*, with local market ranging from $3 to $4 above Savannah on the various grades.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0.65 – $0.75

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.40 —	$1.50
Alpha naphthol, refined	lb.	1.60 —	1.70
Alpha naphthylamine	lb.	.55 —	.60
Aniline oil, drums extra	lb.	.35 —	.40
Aniline salts	lb.	.42 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.90 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.35 —	1.40
Benzidine, sulphate	lb.	1.15 —	1.25
Benzoic acid, U.S.P	lb.	.90 —	1.00
Benzoate of soda, U.S.P	lb.	.80 —	.90
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.40
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.31
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate (nominal)	lb.	3.50 —	4.00
Beta naphthol, sublimed (nominal)	lb.	.80 —	.90
Beta naphthol, tech (nominal)	lb.	.65 —	.85
Beta naphthylamine, sublimed	lb.	2.25 —	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 —	.19
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.10 —	1.20
Cresylic acid, 95-97%, dark, in drums	gal.	1.00 —	1.05
Cresylic acid, 50%, first quality, drums	gal.	.65 —	.75
Dichlorbenzol	lb.	.08 —	.10
Diethylaniline	lb.	1.50 —	1.60
Dimethylaniline	lb.	1.35 —	1.55
Dinitrobenzol	lb.	.30 —	.37
Dinitroclorbenzol	lb.	.30 —	.35
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.40 —	.45
Dinitrotoluol	lb.	.40 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine (nominal)	lb.	.80 —	.85
H-acid (nominal)	lb.	2.25 —	2.50
Metaphenylenediamine	lb.	1.15 —	1.30
Monochlorbenzol	lb.	.18 —	.20
Monoethylaniline	lb.	2.00 —	2.40
Naphthaline crushed, in bbls. (250 lb.)	lb.	.17 —	—
Naphthaline, flake	lb.	.17 —	.18
Naphthaline, balls	lb.	.16 —	.18
Naphthionic acid, crude	lb.	.75 —	.85
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.40 —	.50
Nitro-toluol	lb.	.18 —	.25
Ortho-amidophenol	lb.	3.25 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.35 —	.45
Para-amidophenol, base	lb.	2.50 —	3.00
Para-amidophenol, HCl	lb.	2.50 —	3.00
Para-dichlor-benzol	lb.	.08 —	.12
Paranitraniline	lb.	1.50 —	1.55
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.60 —	3.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.65 —	.75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.20
Pyridin	gal.	2.00 —	3.50
Resorcin, technical	lb.	4.25 —	4.50
Resorcin, pure	lb.	6.25 —	6.75

Salicylic acid, tech., in bbls. (110 lb.)	lb.	$0.—	—	$0.52
Salicylic acid, U. S. P.	lb.	.50	—	.6
Salol	lb.	.90	—	1.00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.27	—	.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.28	—	.32
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities

Beeswax, refined, dark	lb.	$0.36	—	$0.39
Beeswax, refined, light	lb.	.39	—	.40
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1. (nominal)	lb.	1.00	—	1.05
Carnauba, No. 2, regular (nominal)	lb.	.85	—	.88
Carnauba, No. 3, North Country (nominal)	lb.	.43	—	.44
Japan	lb.	.21	—	.22
Montan, crude	lb.	.23	—	.25
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09	—	.09½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.09½	—	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11½	—	.12¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.14½	—	.15
Paraffine waxes, refined, 133-135 m.p.	lb.	.16½	—	.17
Paraffine waxes, refined, 135-137 m.p.	lb.	.17½	—	.18½
Stearic acid, single pressed	lb.	.25	—	.26
Stearic acid, double pressed	lb.	.26	—	.27
Stearic acid, triple pressed	lb.	.27	—	.28

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.80
Pine oil, pure, dest. dist.	gal.	1.60
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.50	—	$18.00
Rosin E-I	280 lb.	18.50	—	19.75
Rosin K-N	280 lb.	20.00	—	21.00
Rosin W. G.-W. W.	280 lb.	21.25	—	23.00
Wood rosin, bbl.	280 lb.	17.00	—	17.00
Spirits of turpentine	gal.	1.85	—	
Wood turpentine, steam dist.	gal.	1.70	—	1.80
Wood turpentine, dest. dist.	gal.	1.40	—	1.50
Pine tar pitch, bbl.	200 lb.		—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	15.00
Retort tar, bbl.	500 lb.	15.00	—	15.50
Rosin oil, first run	gal.	.87	—	.89
Rosin oil, second run	gal.	.89	—	.92
Rosin oil, third run	gal.	1.04	—	1.05
Rosin oil, fourth run	gal.	1.12	—	1.12

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.40
70-72 deg., steel bbls. (85 lb.)	gal.	.38
68-70 deg., steel bbls. (85 lb.)	gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.29

Crude Rubber

Para—Upriver fine	lb.	$0.37½	—	$0.38
Upriver coarse	lb.	28½	—	.29½
Upriver caucho ball	lb.	.30	—	.30½
Plantation—First latex crepe	lb.	.38	—	.39
Ribbed smoked sheets	lb.	.38¼	—	.39
Brown crepe, thin, clean	lb.	.37	—	.38
Amber crepe No. 1	lb.		—	.40

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.18½	—	$0.20
Castor oil, AA, in bbls.	lb.	.20	—	.22
China wood oil, in bbls.	lb.	.18½	—	.19½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.17½	—	.18½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.18½	—	.19½
Corn oil, crude, in bbls.	lb.	.17½	—	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.15½	—	.16
Cottonseed oil, summer yellow	lb.	.18½	—	.19
Coteonseed oil, winter yellow	lb.	.21	—	.22
Linsed oil, raw, car lots (domestic)	gal.	1.57	—	1.67
Linseed oil, raw, tank cars (domestic)	gal.	1.52	—	1.62
Linseed oil, boiled, car lots (domestic)	gal.	1.60	—	1.70
Olive oil, commercial	gal.	3.10	—	3.25
Palm, Lagos	lb.	.12½	—	.13½
Palm, bright red	lb.	.13	—	.13½
Palm, Niger	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.13	—	.15
Peanut oil, refined, in bbls.	lb.	.22	—	.24
Rapeseed oil, refined in bbls.	gal.	1.70	—	1.72
Rapeseed oil, blown, in bbls.	gal.	1.80	—	1.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.17	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.12½	—	.13½

FISH

Winter pressed Menhaden	gal.	$1.17	—	$1.18
Yellow bleached Menhaden	gal.	1.20	—	1.22
White bleached Menhaden	gal.	1.23	—	1.24
Blown Menhaden	gal.	1.30	—	1.32

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Buena Creek, S. C.	net ton	$22.50	—	$25.00
Barytes, ground, off color, f.o.b. Buena Creek	net ton	15.00	—	20.00
Barytes, crude, 88% to 94% ba., Kings Creek	net ton	8.00	—	10.00

Talc, imported	ton	60.00	—	70.00

Refractories

All f.o.b. Works:		
Chrome brick, 9 in. straights and sizes	net ton	$80-90 at Baltimore
Chrome brick	net ton	75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Fire clay	net ton	5—7 at Baltimore
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	85-90 at Chester, Penn.
Magnesite brick, 9 in. straights	net ton	90 at Baltimore
Magnesite brick, 9 in. sizes and shapes larger than 9 in.		Regular extras
Silica brick	1,000	50-55 at Mt. Union, Penn.
Silica brick, 9 in. straights, and sizes	1,000	55, Chicago District

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.17	—	.18
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon	lb.	.18	—	.19
Ferro-manganese, 70-80% Mn.	gross ton	200.00	—	250.00
Spiegeleisen, 16-20% Mn.	gross ton	70.00	—	75.00
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.	lb.	2.25	—	2.75
Ferro-silicon, 10-15%	gross ton	60.00	—	65.00
Ferro-silicon, 50%	gross ton	80.00	—	90.00
Ferro-silicon, 75%	gross ton	150.00	—	160.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90	—	1.10
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	7.00	—	
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50	—	7.75

Ores and Semi-finished Products

All f.o.b. Mines, Unless Otherwise Stated

Carnotite 96% U_3O_8, per lb. of U_3O_8	lb.	$2.75	—	$3.00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	unit	.60		.65
Chrome ore, 40%, min., Cr_2O_3, f.o.b. Atlantic Seaboard	unit	.70	—	.85
Coke, foundry, f.o.b. ovens	net ton	16.00	—	17.00
Coke, furnace, f.o.b. ovens	net ton	15.00	—	16.00
*Coke, petroleum, refinery, Atlantic Seaboard	net ton	24.00		
Fluor spar, gravel	net ton	22.50	—	25.00
Fluor spar, lump, f.o.b. Tonuco, New Mexico	net ton	17.50	—	
Fluorite, 52% CaO_2 per lb. ore	lb.	.02	—	
Manganese ore, 45% Mn and over	unit	.80	—	.85
Manganese ore, chemical (MnO_2)	gross ton	75.00	—	85.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.85	—	
Monazite, per unit of ThO_2	unit	4.00	—	
Pyrites, Spanish, fines, c.i.f.	unit	.12	—	
Pyrites, Spanish, furnace size, c.i.f.	unit	.11	—	
Pyrites, Spanish, run of mines, c.i.f.	unit	.12	—	.14
Pyrites, domestic, fines	unit	.12	—	.14
Rutile, 95% TiO_2 per lb. ore	lb.	.20	—	.25
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00		
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50	—	7.50
Uranium oxide, 96% per lb. contained U_3O_8	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	12.00	—	14.00
Vanadium ore per lb. of V contained	lb.	1.00	—	3.00
Zircon, washed, iron free	lb.	.10	—	.12

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

LOS ANGELES — The Robertson Cole Studios, Inc., Currier Bldg., has awarded the contract for the construction of a moving picture studio on Gower St. and Melrose Ave., to the Milwaukee Bldg. Co., 403 South Hill St. A chemical laboratory will be installed in same. Estimated cost, $100,000.

SAN PEDRO—The Fabri-Cord Tire Co., 917 Natl. Bank Bldg., Los Angeles, has purchased a site on 17th St. and plans to build a 3-story, 60x250-ft. factory on same. Estimated cost, $2,000,000. S. H. Christian, pres.

Connecticut

FAIRFIELD—The Bridgeport Deoxidized Bronze & Metal Co., Iran Ave., has purchased a 23-acre site along the New York, New Haven & Hartford R.R., here, and plans to construct a large bronze factory on same.

MONTVILLE—The Robert Gair Paper Corp., Thames River Division, will soon award the contract for the construction of a 2-story, 250x400-ft. manufacturing building. Estimated cost, $500,000.

Illinois

CHICAGO—The Kroeck Paper Co., 220 Institute Pl., is building a plant at Paulina and Superior Sts. Estimated cost, $240,000.

Indiana

WEST HAMMOND—R. G. Pierce, archt., 10 South La Salle St., Chicago, will soon award the contract for the construction of a 1-story, 210x560-ft. steel plant, here, for the La Salle Iron Works, 2305 South Halsted St., Chicago. Rolling mill, heat treatment and pickling equipment will be installed in same. Estimated cost, $650,000.

Iowa

HAWARDEN—The Bd. Educ. rejected all bids for the construction of a 2-story, 60x150-ft. school including chemical and physical laboratories. Estimated cost, $135,000. G. L. Lockhart, 391 Endicott Bldg., St. Paul, Minn., archt.

Maine

CARIBOU—The Aroostook Federation of Farmers plans to build a large fertilizer plant here. Estimated cost, $50,000.

Maryland

BALTIMORE—The Natl. Enameling & Stamping Co., Race and Ostend Sts., has awarded the contract for the construction of a 2-story, 61x76-ft. addition to its tin stamping factory, to the John Waters Bldg. Co., 23 East Center St., at $100,000.

Massachusetts

CAMBRIDGE—The Ltd. Plate Glass Co., 30 Sudbury St., Boston, has awarded the contract for the construction of a 2-story, 100x200-ft. factory on Albany St., to N. H. & H. A. Root, 6 Beacon St., Boston.

Michigan

DETROIT — The International Metal Stamping Co., Artillery & Muster Aves., has awarded the contract for the construction of a 1-story, 79x532-ft. factory on Artillery Ave., to the H. G. Christman Co., 315 Stevens Bldg., at $130,000. Noted June 9.

Missouri

BROOKFIELD—The School Bd. plans to build a school. A general chemical laboratory will be installed in same. Estimated cost, $165,000. A. W. Baker, secy. W. E. Hulse & Co., 309 Securities Bldg., Des Moines, Ia., archt.

NEVADA—T. B. Craig, Supt. of State Hospital 3, will receive bids until July 1 for the construction of a 2-story, 40x80-ft. hospital. A bacteriological laboratory will be installed in same. Estimated cost, $60,000.

New York

GREYCOURT—The Dept. of Correction, Municipal Bldg., New York City, rejected all bids for furnishing all labor and material for the construction of a sewage disposal plant for the New York Women's Farm Colony here. Work will be re-advertised. Noted May 5.

North Dakota

BISMARCK—The Bd. of City Comrs. will receive bids until July 12 for the construction of a complete waterworks system, including a 79x114-ft. filtration plant and a 73x113-ft. sedimentation basin, rapid sand filters of 750,000-gal. capacity, dry feed chemical machines, etc.

JAMESTOWN—The Bd. Educ. is having plans prepared for the construction of a 3-story, 230x240-ft. junior high school. A chemical laboratory will be installed in same. Estimated cost, $200,000. Shannon Boyd & Boyd, archts.

Ohio

AKRON—The city received only bid for furnishing sulphate and aluminum to the bureau of water service and water supply, Dept. of Pub. Serv., from the General Chemical Co., 112 North Adams St., $25,800.

AKRON—E. A. Zeisloft, Dir., of Pub. Serv., Delaware Bldg., will receive bids until July 9 for the construction and equipment of an addition to the water purification plant. Filter equipment will be installed in same.

GARRETTSVILLE—The McWade Tire & Rubber Co., 711 Union Bldg., Cleveland, plans to build a 2-story rubber factory here. Estimated cost, $75,000.

MASSILLON—The Alloy Electric Steel Castings Co. has awarded the contract for the construction of a 1-story, 50x150-ft. mill building, to the Boldt Constr. Co., 6110 Euclid Ave., Cleveland, at $60,000.

WORTHINGTON — W. P. Vest, village clk., will soon award the contract for the construction of a sewage disposal plant for the city. Jennings, Laurence Co., Hartman Bldg., Columbus, engrs.

Texas

BRIDGEPORT—The Phoenix Clay Corp., 1215 Southwestern Life Bldg., Dallas, plans to build a brick and tile plant here, which will have a daily capacity of 125,000 brick or 150 tons of tile. Address C. W. Martin, pres.

FARMERSVILLE—The Bd. of Directors of the Farmersville Sewer Co. has awarded the contract for the construction of sanitary sewer lines and 2 sewage disposal plants, to J. W. Crook, Paris, at $43,856. Noted June 16.

Wisconsin

MILWAUKEE—The Amer. Metal Products Co., Clinton St. and Kinnickinnic Ave., has purchased a 6-acre site on Burham St. and plans to construct a modern 80x220-ft. foundry on same. Later the company plans to build a rolling mill. C. J. Zarse, genl. mgr.

MILWAUKEE—The Supt. of Lighthouses will soon award the contract for furnishing and delivering acetylene gas in acetone, gasoline, kerosene, etc.

PORT WASHINGTON—The Turner Mfg. Co. will soon award the contract for the construction of a 1-story, 150x160-ft. foundry and factory addition. Frank D. Chase, Inc., 645 North Michigan Ave., Chicago, archt. Noted June 23.

New Brunswick

MONCTON—The Record Fdry. & Machine Co., Ltd., plans to build a 50x140-ft. foundry. Estimated cost, $75,000. H. G. Jackson, mgr.

Ontario

KANORA—The St. Francis Pulp & Paper Co. will soon receive bids for the construction of a pulp and paper mill along the English River north of here. Estimated cost, $5,000,000.

LONDON—The city plans to supply St. Thomas and London with water from Lake Erie. Estimated cost of pipe line, $3,000,000. Plans include a filter plant at an annual charge of $500,000.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold its summer meeting at the La Salle Hotel in Chicago, Aug. 16, 17 and 18.

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS is holding its twelfth semi-annual meeting as follows: June 28 and 29 in Montreal, June 30 in Ottawa, July 1 in Ontario, July 2 in Shawinigan Falls, July 3 in La Tuque, July 4 in Chicoutimi and July 5 in Quebec.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

THE AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

THE FOREST PRODUCTS LABORATORY will hold its decennial celebration at Madison, Wis., July 22 and 23, 1920.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INSECTICIDE AND DISINFECTANT MANUFACTURERS' ASSOCIATION will hold its mid-summer meeting at Boston, July 15 and 16.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Contents

A Comparative Test Upon High-Speed Steels—I 829
By A. J. Langhammer.
Notes on a Competition made by Packard Motor Car Co. of modern high-speed steels. Preliminary observations on current sales practices and a general review of various classes, and the effect of chemical compositions and heat treatment.

Operation of the Gainesville Castor Oil Plant 833
By J. H. Shrader and A. C. Goetz.
A Description with many details of the expeller and solvent extraction process of obtaining a high recovery of oil from castor beans. Cleaning and tempering beans. Drying and bleaching oil. Cake extraction and operating difficulties.

Supply of Inorganic Nitrogen in the United States 841
By Major D. P. Gaillard.
The Inadequate Domestic Supply of nitrogen in the United States is supplemented by importations from Chile. Summary of figures on consumption and supply showing deficiency even if Government plants are operated.

Synthetic Acetic Acid and Acetone 847
By J. T. Rooney.
Description of the process and method of production of acetic acid, acetates and acetone from calcium carbide. Acetylene generation and catalytic hydration. Oxidation of acetaldehyde to acetic acid. Acetone.

The Commercial Synthesis of Sillimanite 851
By Andrew Malinovszky.
A Description of a cupola process for fusing alumina and silica to form sillimanite crystals. Reactions consist of forming carbides under reducing, and combusting them under oxidizing conditions.
